MODEL ELECTRICAL FARM WILL ADJOIN CHICAGO.—A model electrical farm of 80 acres is being developed by the Public Service Company of Northern Illinois a few miles out of Chicago. All of the buildings, including the farm home, will be built to specifications which include provision for all modern electrical applications. The house and barn will be wired according to "red seal" specifications. The farm will be operated by a practical farmer on a business basis in addition to being open for inspection and study. It is expected that it will be in complete operation early in the summer.

SAN FRANCISCO TO VOTE ON PUBLIC UTILITY COMMISSION ISSUE. — The Board of Supervisors of San Francisco has voted to place on the ballot at the primary election Aug. 28 a measure to permit voters of the city to decide whether they wish to create a public utility commission to administer and direct the water, light, power, heat and transportation utilities of the city. The measure was to have gone on the ballot at the next November general election. An attempt to change the provision fixing the commission at three members, and increasing it to a greater number, was decisively defeated at the board meeting.

FACT-FINDING POWER INVESTIGATION FOR MAINE.—The Maine section of the New England Council has appointed a fact-finding commission to investigate all phases of the power question as it affects that state. The commission is composed of William T. Cobb of Rockland, Philip Dana of Westbrook, James C. Boyd and Benjamin F. Cleaves of Portland, William I. Cummings of South Berwick, Leslie E. McIntire of Waterford and Robert J. Peabody of Lubec. The commission will not make recommendations, but the results of its inquiry will, it is expected, throw light on whether or not electrical energy should be sold for use outside the state.

WORK ON SLAVE FALLS PLANT ON WINNIPEG RIVER TO BEGIN SOON.—Preliminary development of the Slave Falls power site, on the Winnipeg River, in the Province of Manitoba, by the Winnipeg public hydro system will be begun soon, a year in advance of schedule, owing to the increased demand for electrical power from the city-owned utility. It is expected that development will be completed by 1931, at an estimated expenditure of $7,000,000. The Slave Falls site is 90 miles northeast of Winnipeg and 5 miles from the Pointe du Bois plant of the city hydro system. This is the last undeveloped power site on the Winnipeg River available to the public hydro enterprise. It will more than double the city's production of electrical energy and round out a twenty-five-million-dollar investment. There is available at the Slave Falls site a total of 36,480 continuous horsepower under conditions of ordinary minimum flow and more than 60,000 continuous horsepower at ordinary six-month flow. The head at this site is 26 ft.

## *Coming Meetings*

**[A complete directory of electrical associations, with their secretaries, is published in the first issue of every volume. For latest list see ELECTRICAL WORLD for Jan. 7, page 80.]**

Southwestern Public Service Association—Dallas, Tex., May 2-5. E. N. Willis, 403 Slaughter Bldg., Dallas, Tex.

American Institute of Electrical Engineers—New Haven regional meeting, May 9-11; national convention, Cosmopolitan Hotel, Denver, June 25-29. F. L. Hutchinson, 33 West 39th St., New York.

Middle West Division, N. E. L. A.—Hotel Statler, St. Louis, May 9-11. T. A. Browne, 1519 O St., Lincoln, Neb.

Arkansas Utilities Association—Arlington Hotel, Hot Springs National Park, May 14-16. R. I. Brown, Arkansas Power & Light Co., Little Rock.

American Society of Mechanical Engineers—Pittsburgh, May 14-17. Calvin W. Rice, 29 West 39th St., New York.

Indiana Electric Light Association (jointly with Indiana Public Utilities Association) — Columbia Club, Indianapolis, May 22-24. William Stokes, 1548 Consolidated Bldg., Indianapolis.

National Electric Light Association—Atlantic City, June 4-8. P. S. Clapp, 420 Lexington Ave., New York.

American Association of Engineers—Hotel Hussman, El Paso, Tex., June 4-6. M. E. McIver, 63 E. Adams St., Chicago.

Electrical Supply Jobbers' Association—The Homestead, Hot Springs, Va., June 5-8. E. Donald Tolles, 165 Broadway, New York.

National Electrical Manufacturers' Association—The Homestead, Hot Springs, Va., June 11-15. S. N. Clarkson, 420 Lexington Ave., New York.

Pacific Coast Division, N.E.L.A. — Hotel Huntington, Pasadena, Cal., June 12-15. S. H. Taylor, 447 Sutter St., San Francisco.

Georgia Electrical Association—Savannah, June 14 and 15. J. J. McDonough, Georgia Power Co., Dublin, Ga.

Northwest Division, N.E.L.A.—Portland, Ore., June 19-22. B. Snow, 1208 Spalding Bldg., Portland, Ore.

Canadian Electrical Association—SS. "Richelieu" from Montreal to Saguenay and return, June 20-23. H. M. Lyster, 712 Power Bldg., Montreal.

American Society for Testing Materials — Chalfonte-Haddon Hall, Atlantic City, N. J., June 25-29. C. L. Warwick, 1315 Spruce Street, Philadelphia.

SAN DIEGO COMPANY MAKES RATE REDUCTIONS TOTALING $400,000 A YEAR.—Customers of the San Diego Consolidated Gas & Electric Company will benefit immediately to the extent of more than $400,000 a year as the result of reductions in electric and steam rates that went into effect on April 20. These new rates are based on an inquiry by the California Railroad Commission and the report of its engineering department that the company earning in 1927 was substantially $400,000 in excess of a net return of 7½ per cent on its investment, with which the company expressed itself content. The speedy conclusion of the case, with its substantial saving to the consumers, is believed to establish a record in the matter of quick handling of a formal rate matter of such importance. Reductions for the various classes of business are approximately as follows: Lighting, 11.4 per cent; general power, 11.1; agricultural power, 15.2; street lighting, 6.3; electric railway, 7.5; steam heating, 8.6.

OPTIONAL TARIFF FOR UPSTATE NEW YORK CUSTOMERS.—Optional rates for domestic consumers, offering a sliding-scale reduction with a minimum monthly rate of $3.50, are announced by the New York Central Electric Corporation, serving Perry, Auburn, Geneva, Hornell and many other communities in western New York. Under the optional schedule clients pay 10 cents per kilowatt-hour for the first 25 kw.-hr. a month, 8 cents for the second 25 kw.-hr., 6 cents for the third, 4 cents for the fourth and 3 cents for the remainder. The regular rate is 11 cents per kilowatt-hour for the first 50 kw.-hr., with corresponding reductions for quantity consumption. The minimum monthly rate is $1. The optional schedule is designed to encourage average consumers to use electrical household devices.

INTERCONNECTION GOES ON APACE IN TEXAS.—The installation of the new generating unit in the power plant of the Comal Power Company, at New Braunfels, Tex., to bring its capacity to 60,000 kw., will take about fourteen months and cost $2,000,000. Completion of the new installation will give the San Antonio Public Service Company a combined total of 100,000 kw. at New Braunfels and San Antonio. The San Antonio Public Service Company is interconnected with the Central Power & Light Company south of New Braunfels and with the Texas Power & Light Company, serving communities north of New Braunfels, and it is now constructing a line from New Braunfels to Luling to meet the Texas Power & Light system on the east. The Texas Power & Light Company is understood to plan the immediate construction of another 132,000-kw. line from its Trinidad station to a proposed new substation at

Milano Junction and a 60,000-kw. line from Milano Junction to Cameron. This will give that company a double transmission circuit into Temple. A 60,000-kw. line will run from Luling to Taylor and connect with the Insull lines by way of Seguin.

**Oswego (N. Y.) Hydro Plant Starts Next Week.**—The hydro-electric plant at Oswego, N. Y., at Dam No. 6 on the Oswego River will be started on May 1. The plant has been constructed at a cost of approximately $1,000,000 by the Carlisle interests, which will operate it on a 25-year lease made a year ago, paying the city of Oswego in rent $50,000 a year. The plant will have a capacity of 7,500 hp., to be produced by three 2,500-hp. generators, with additional wheel pits for two more wheels, should the city at some future time obtain the right to develop the other one-half flow of the river, for which application has been made to the authorities at Albany.

**Salt Lake Has Successful Electrical Gathering.**—The seventh annual convention and "get-together" of the representatives of the various branches of the electrical industry in Salt Lake City and adjacent territory was held on March 28, at the Newhouse Hotel, under the auspices of the Electrical League of Utah, and proved the most successful yet held. R. M. Bleak, president of the league; B. E. Rowley, former president; R. R. Reid, president of the local contractors and dealers' association; W. M. Scott, superintendent of lines and service of the Utah Power & Light Company's Salt Lake division; City Attorney William H. Folland of Salt Lake City, who discussed city ordinances; L. B. Gowan, of the Lighting Service Bureau; Clyde L. Chamblin, president of the Association of Electragists International, and Adam S. Bennion of the Utah Power & Light Company were speakers. About three hundred guests attended the dinner, at which George R. Randall was toastmaster.

**Ireland Plans Distribution of Shannon Energy.**—In a report just issued by the Electricity Supply Board of the Irish Free State plans are outlined for the distribution of energy from the River Shannon, which will become available next year. A start will be made in Dublin, where the existing network will be used. The municipal undertaking will connect its transformer station with that which is being built by the Shannon board, and the work of switching over will present no difficulty. Cork and Limerick will be tackled almost immediately, while the board is negotiating for the acquisition of the authorized undertakings in Dundalk, Wexford and Clonmel. In the opinion of the board the interest of the country will be served best by the acquisition of all existing undertakings by the state. The board has mapped out an ambitious program for the electrification of 130 towns and villages in the Free State.

# Recent Court Decisions

**To Recover for Personal Injuries on Specific Allegation of Negligence There Must Be Proof.**—The Supreme Court of Iowa sustained a directed verdict for the defendant in Rauch vs. Des Moines Electric Company, a damage suit brought because the plaintiff, who had climbed upon one of the company's lighting poles to view a parade, was injured by the falling of a globe upon his head. He sued for compensation, claiming that the dislodgment of the globe was due to its being insecurely attached to its bracket; but the courts found the contention unproved and pointed out that a specific allegation of this nature does not come under the doctrine of *res ipsa loquitur* ("the thing speaks for itself.") (218 N. W. 340.)*

**Children Cannot Climb Company's Poles at the Company's Risk.**—If parents permit their children to climb a public utility company's poles, they do so at their own risk, according to a decision of the Superior Court at Los Angeles. The ruling was made in connection with a damage suit for $75,000 brought by Harry K. Brown against the Southern California Edison Company because of the death of Brown's son, a boy of twelve, who climbed one of the defendant's poles and was killed. The court ruled: "With the development of electrical power and high-tension transmission lines it would be a dangerous precedent to relieve parents of responsibility and hold electrical distributing companies responsible for lack of knowledge or carelessness of a child of twelve which leads him to climb a pole which he ought to know was not put there for that purpose. To hold the companies liable would mean that they would be punished for the negligence of others."

**Complaint of Interference with Stream by Upper Riparian Owner Must Allege Unreasonable Use of Water as Matter of Law.**—The New York Supreme Court, Special Term, has dismissed the complaint in Maylender vs. Fulton County Gas & Electric Company, in which the company, as the upper riparian owner on Peck Creek, was charged with an unjustifiable interference with stream flow. Failure to allege that the company's works were not built in conformity with the fall of land, or were not adapted to the character of the stream, or were improperly operated, or that diversion of waters caused stream to overflow on plaintiff's land, or that plaintiff had ever used the waters of the stream or ever intended to do so, led, the court said, to the assumption that the dam was properly constructed and therefore that the lower riparian owner had no cause of action. (227 N. Y. S. 209.)

**When Is Contributory Negligence a Matter of Law?**—Affirming a judgment for the plaintiff in Beman vs. Iowa Electric Company, a damage suit brought because of the death of plaintiff's husband from electric shock, the Supreme Court of Iowa said that the alleged contributory negligence was for the jury to pass on and that contributory negligence becomes a question of law, for the judge, only when it is so flagrant as to be evident to any reasonable person. In this case the man was one of a bridge crew working near a 13,200-volt transmission line belonging to the company. The company had been asked to move its line and had done so, but apparently not far enough, since, although fellow workmen gave evidence that they had tested the operation of the boom which the victim was guiding and found an 18-inch clearance between it and the electric wire, it was proved that death resulted as stated above. Proof that there had been no contact between the boom or cable of the derrick and the wire and testimony that electricity transmitted at 13,200 volts will not arc or jump over a gap from an unbroken continuous wire were not held by the court to substantiate the company's defense, the "thing speaking for itself." (218 N. W. 343.)

# Commission Rulings

**Commission Insists that 95 per Cent of Consumers in Small Community Shall Have Metered Service.**—Meters are the best gage for determining what an electric consumer should pay for the service he receives, the North Dakota Board of Railroad Commissioners has held in the case of a complaint by citizens of Litchville against J. M. Haarsager, the operator of the electric light plant at that place. The petitioners asked for increased hours of electric service and reduction in the rate. The commission learned that some of the consumers had meters which they owned themselves while others received service at a flat rate. The company was directed to take over all meters within the next year and to put other consumers on a metered basis within 90 days, so that not more than 5 per cent of the consumers would remain on a flat-rate basis.

**Condemns Delay in Applying for Certificate Until Competition Is Threatened.**—In granting a certificate of public convenience and necessity to the Pacific Gas & Electric Company to operate a gas-distributing system in Irvington and contiguous territory and denying the application of the Alameda County Gas Company for a similar certificate, the California Railroad Commission reaffirmed its disapproval of a public utility waiting until threatened competition develops before making application to serve new territory. "A utility owes a duty to that portion of the public which seeks to obtain service as well as to that portion of the public which is already being served," the commission said. "In the case before us there is no question that the Pacific Gas & Electric Company made its offer of service only to forestall competition and filed its application for a certificate of public convenience and necessity only when forced to do so. For that reason it cannot urge a superior right to serve a territory which it has heretofore shown no disposition to enter. Much as the commission might look with favor upon the efforts of a new utility to develop an unserved territory, we are compelled in this instance, on account of the great disparity in rates and certain elements of financial ability, to grant the application of the Pacific Gas & Electric Company."

# News About Men of the Industry

## *N. A. Carle Resigns*

Nathaniel A. Carle, vice-president in charge of operations of the Public Service Production Company, Newark, N. J., has resigned. He is planning to make a trip to Leland Stanford University in California, of which institution he is a trustee, returning East in three months. For a number of years Mr. Carle has been an outstanding figure in the electrical industry, not only as an executive of one of the largest electric utilities in the country but also as a leader in the work of the national engineering organizations. He became identified with the Newark properties in 1912 as chief engineer of the Public Service Electric Company, in this capacity reorganizing and enlarging the engineering staff with noteworthy results along both technical and economic lines. In 1922, when the Public Service Production Company was organized, be became vice-president and general manager and two years later he was named vice-president in charge of operations.

*N. A. Carle*

Mr. Carle was born in Portland, Ore., and was graduated from Leland Stanford University. His early engineering activities carried him to Alaska, Canada, New England, Colorado and New York. Mr. Carle has given unstintingly of his time and energy to association affairs, having been an indefatigable worker as chairman and member of numerous committees. He is past-chairman of the Technical National Section of the National Electric Light Association, a fellow and a past-vice-president of the American Institute of Electrical Engineers and is active in the American Society of Mechanical Engineers, the Association of Edison Electric Illuminating Companies, the Institute of Radio Engineers and the American Electric Railway Association.

---

O. W. MATTISON, formerly manager of the Missouri Power & Light Company in the Mexico district, is now in charge of the Dakota properties of the United Public Service Company with headquarters in Bismarck, N. D. PAUL C. EKERN of Brookfield will succeed Mr. Mattison in Mexico and J. F. DUNCAN of Edina will succeed Mr. Ekern in Brookfield.

HUEY P. LONG, a member of the Public Service Commission of Louisiana, has been elected Governor of that state on the Democratic ticket. Mr. Long was elected a member of the Railroad Commission of Louisiana in 1918, serving on that body until the Louisiana Public Service Commission was created in 1921, when he became a member of that commission. Three years later he was elected to a six-year term.

BANCROFT GHERARDI, chief engineer of the American Telephone & Telegraph Company and president of the American Institute of Electrical Engineers, and Jacob F. Schoellkopf, chairman of the board of directors of the Buffalo, Niagara & Eastern Power Corporation, Buffalo, N. Y., have been nominated to fill two vacancies on the board of trustees of Cornell University. The vacancies will occur in June, when the terms of John L. Senior of Chicago and Judge Cuthbert W. Pound of Lockport, N. Y., will have expired.

ROBERT L. FITZGERALD, manager of the light and power department of the Indiana Service Corporation, Fort Wayne, Ind., since 1924, has resigned his position with that company, effective April 30. Mr. Fitzgerald plans to enter business with B. O. Fink and Jack Fulton in the Auburn Stoker Corporation, Auburn, Ind., manufacturing and marketing automatic smokeless coal burners for heating and industrial boilers. He was formerly associated with the Gary (Ind.) Heat, Light & Water Company, the engineering staff of the Wisconsin Railroad and Tax Commission and with R. M. Feustel, consulting engineer.

ELMER A. SPERRY, inventor and engineer, has been awarded the Holley medal by the American Society of Mechanical Engineers for his achievements in the invention of the gyroscope. Frequent recognition has been given Mr. Sperry for his engineering accomplishments in the form of honorary degrees, medals and membership in scientific societies. In the course of his distinguished career he has been the recipient of the John Scott legacy medal and premium, the John Fritz medal, the Franklin medal and the American Museum of Safety medal. Mr. Sperry was decorated by Czar Nicholas II. of Russia for navigational equipment and he received the Order of the Rising Sun from the Emperor of Japan in 1922. Presentation of the Holley medal will be made May 16 at a dinner which is to be held during the spring meeting of the American Society of Mechanical Engineers in Pittsburgh.

## *Theodore Beran Retires*

Theodore Beran, commercial vice-president of the General Electric Company in charge of the New York district, has asked to be relieved of the responsibilities of his office May 1, having voluntarily decided to retire from active business life. In commenting on Mr. Beran's retirement J. G. Barry, vice-president of the company, said: "During his long and valuable service, extending over a period of more than 39 years, he has devoted himself wholeheartedly to the company's interests in building up its business in the important territory of which he was the principal commercial executive."

Mr. Beran was born in Springfield, Mass., and was educated in the public schools of New York City, later receiving an A.B. degree from the College of the City of New York. He joined the Sprague Electric Railway & Motor Company in New York in 1889 and when that company consolidated with the Edison interests in 1890 he continued with the Edison General Electric Company and with the General Electric when it was formed in 1892 from the consolidation of the Edison and Thomson-Houston interests. In 1904 he removed to Rugby, England, where he organized the commercial department of the British Thomson-Houston Company. In the fall of 1903 he was made acting manager of the New York district for the General Electric Company, a year later being designated district manager. It was in 1926 that he was named commercial vice-president. Mr. Beran is an associate member of the American Institute of Electrical Engineers, vice-president of the Electrical Board of Trade and a past-president of the New York Electrical Society.

*Theodore Beran*

---

L. J. EDMONSTON, representing the Missouri Power & Light Company at Plattsburg, Mo., has been appointed manager of the Edina office.

### *S. E. Wolff Removes to Oklahoma*

Samuel E. Wolff, consulting engineer, of New York, has disposed of his utility interests in the East to become president of the Oklahoma Power & Water Company, organized by the Colvin interests, with headquarters in Sand Springs. Mr. Wolff has had many years experience in public utility operation in the East and in the Middle West, particularly in Michigan, where he was born and where he was identified with the properties now new constituent units of the Consumers Power Company. After serving in various departments he resigned as general manager of the Jackson (Mich.) Gas Company to take a similar position in charge of the gas, electric and railway utilities in Saginaw and Bay City, Mich. In 1908 he joined the New York executive staff of Hodenpyl, Hardy & Company, managers of the Michigan properties, and continued in the discharge of various functions for them until the end of 1921, when he engaged in some industrial work for a group of New York bankers. Recently he has operated properties in the East and has done financial and consulting work with offices in New York City. Mr. Wolff is a past-president of the Michigan Gas Association, a member of the American Gas Association and of the National Electric Light Association, the insurance committee of which he organized several years ago.

*S. E. Wolff*

**Herman Hill**, for many years consulting electrical and mechanical engineer, is now identified with the Perfection Appliance Company, a subsidiary of the Splitdorf-Bethlehem Electrical Company. Mr. Hill is a practical inventor, his patents totaling more than one thousand.

**Frank J. Doyle**, chief engineer of the Northern States Power Company at St. Cloud, Minn., for 3½ years, has been transferred to Sioux Falls, S. D., to manage the plant there operated by the Northern States company. He was assistant chief at Sioux Falls for 6½ years before removing to St. Cloud. Succeeding Mr. Doyle at St. Cloud as chief engineer will be L. H. Lawrence of Sioux Falls.

**T. F. Bowdern** is now head of the public relations department of the Arkansas-Missouri Power Company, the East Missouri Power Company and the Missouri Public Service Company, all controlled by the Inland Power & Light Company.

### *Moloney and Mullen of St. Louis Resign*

T. O. Moloney and James J. Mullen have resigned as president and vice-president of the Moloney Electric Company, St. Louis, Mo., effective June 30, to devote more time to their personal affairs. During the 30 years in which they have been connected with the company it has grown to be one of the largest transformer manufacturers in the United States with unusually well-equipped factories, having recently completed a large plant in the industrial district of St. Louis. Mr. Moloney and Mr. Mullen will continue as members of the board of directors and in an advisory capacity. F. H. Barrington will be in active charge of the management of the company, assisted by W. M. Cory, both of whom are identified with the company at the present time.

Mr. Moloney's activity in the electrical industry dates back to 1890, when he became connected with the electrical department of the Laclede Gas Light Company of St. Louis. The existing type of transformer engaged his special attention and through these studies he quickly obtained the experience which enabled him to contribute substantially to the evolution of the modern, well-balanced transformer. From these beginnings resulted the Moloney Electric Company, organized in 1897 with Mr. Moloney as president.

### *H. D. Savage Heads Combustion Engineering*

H. D. Savage, for many years vice-president of the Combustion Engineering Corporation, New York, has been elected president to succeed Joseph V. Santry, resigned. Mr. Savage brings to his new office a long and varied experience in the manufacture and sale of power plant equipment. He has been identified with the development of pulverized fuel-burning equipment since its very inception and is recognized as an authority on this subject. When the Combustion Engineering Corporation purchased the Lopulco Pulverized Fuel Systems, in 1920, Mr. Savage became associated with this organization as the directing head of the pulverized fuel division. In addition to the presidency of the Combustion Engineering Corporation Mr. Savage holds executive positions in a number of the subsidiary companies of the corporation. He is a member of the American Society of Mechanical Engineers, American Society of Mining and Metallurgical Engineers and of the Franklin Institute.

*H. D. Savage*

## Obituary

**Howard F. Thurber**, formerly president of the New York Telephone Company, died at his home in New York April 21 of pneumonia. Mr. Thurber was made chief executive of the telephone company in 1919 after spending practically his entire business life in the service of Eastern telephone companies. He occupied the office of president for five years and subsequently became chairman of the board of directors. Mr. Thurber was a native of Brooklyn, N. Y., and received his technical training at the Brooklyn Polytechnic Institute and at Cornell University. He was a member of the A.I.E.E.

**Elias E. Ries**, engineer-inventor, died of pneumonia at his home in New York April 20 after an illness of one week. Mr. Ries was prominently identified with the very beginnings and with the development of electrified railroads and rapid transit in New York and other cities. He was also a pioneer in the electric light industry in New York, from 1880 to 1884, having been affiliated with S. Bergmann & Company, the Edison company, the U. S. Electric Illuminating Company and with the Fuller Manufacturing Company.

**Alexander D. Lunt**, manager of the patent department of the General Electric Company since 1922, died in Atlantic City, N. J., April 25. He had been ill since December. A native of Biddeford, Me., Mr. Lunt received his technical education at Worcester Polytechnic Institute and at Cornell University. Previous to joining the General Electric patent department in 1898 he was connected with the United States Patent Office at Washington.

# Financial and Statistical News

## *Common Stocks Rise Steadily Refunding Program Large*

THE investor who has had sufficient foresight to add a sprinkling of utility common stocks to his holdings during the past few months has been amply repaid, assuming, of course, a reasonable degree of diversification. It would be difficult to pick a group of power and light stocks in which a handsome appreciation has not taken place, even since the beginning of the current year. A representative group of fifteen leading stocks averages 142 at present, against 122 at the first of the year. The same group averaged 95 at the beginning of last year. Among the individual members of the group gains of as much as 45 points were made since the beginning of this year. The market continues exceedingly strong.

Refunding and retiring of high-priced issues continues on a large scale. More than $116,000,000 of power and light company bonds were called in April. A large number of these were 6s and 7s. According to predictions, bond redemptions for May will be unusually heavy in the power and light industry. Several large issues will be replaced with money costing anywhere from ½ per cent to 2 per cent less and annual charges will thus be materially reduced.

## America Financing Big British Electricity Trust

Will the supply of electricity for lighting and power purposes in southern England (excluding London) eventually come under the control of one great trust supported and financed by American capital? This question is becoming one of great interest in British electrical circles at the present time. As straws indicate the direction of the wind, so it is thought do the many facts available indicate the trend of events.

The keynote of the situation is declared to be the Greater London and Counties Trust, Ltd., which is said to have behind it practically unlimited American capital. Already this trust has a controlling interest in the East Anglian Electricity Company, the Oxford Electric Company and Edmundsons' Electricity Corporation, Ltd. It will also control the Bedfordshire, Cambridgeshire and Huntingdonshire Company, which is not yet operating, but owns bulk supply powers within the area embraced by its title, and the Wessex Electricity Company. This, again, is not yet operating, but holds bulk supply powers within the counties of Oxford, Buckinghamshire, Berkshire, Wiltshire and Gloucestershire. It is also promoting a bill in Parliament to increase its area by including, *inter alia*, Devon and Cornwall.

How much farther the operations of the trust will extend cannot be stated at present. All that is known is that during recent months there has been a persistent purchasing of the shares of bulk supply and distributing companies in southern England at prices which have little regard for present dividends.

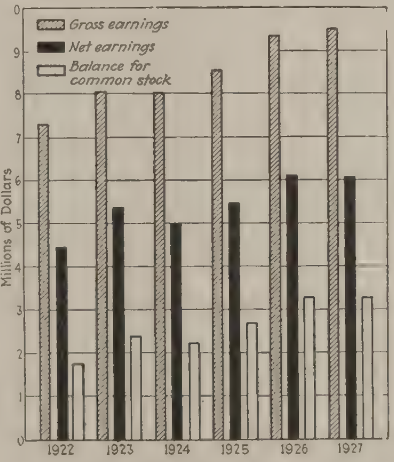
The latest development is the notification of the Sevenoaks Electricity Company of an offer to purchase its entire issued capital. No indication is given as to the identity of the potential purchaser, but shareholders have been advised not to part with their holdings. It is worth noting that the area in which the company operates is within the bulk supply area of one of the associated companies of the County of London Electric Supply Company.

## Virginia Electric Plans New Issues

To care for possible future financial requirements the directors of the Virginia Electric & Power Company have been authorized to issue, in their discretion, $8,000,000 in first and refunding mortgage gold bonds of the company, which will increase the aggregate to $20,000,000. This action was taken at the annual meeting of the stockholders. The directors also were authorized to petition the State Corporation Commission to permit amendment of the company's charter so as to provide for an increase of $5,000,000 in 6 per cent cumulative authorized preferred stock. Possibly $3,000,000 in 6 per cent preferred will be issued this year.

## Montana Power Gross Earnings Advance Slightly Over 1926

AS A result of curtailment of copper production last year the Montana Power Company, showed an increase of only 2 per cent in gross and an actual decline in net earnings as well as in surplus over charges. Completion of an electrolytic zinc plant by the Anaconda Copper Mining Company, however, is expected to add $750,000 to income yearly. Furthermore, important economies are expected to result from merger with the American Power & Light Company, on which plan the shareholders are asked to pass this week.



*Earnings of Montana Power Company covering six-year period*

| | 1926 | 1927 |
|---|---|---|
| Gross earnings | $9,339,189 | $9,518,728 |
| Operating expense | 3,208,551 | 3,437,638 |
| Net earnings | $6,130,638 | $6,081,090 |
| Interest | 1,826,610 | 2,168,387 |
| Surplus | $4,304,028 | $3,912,703 |
| Depreciation | 350,000 | 300,000 |
| Balance | $3,954,028 | $3,612,703 |
| Preferred dividend | 684,922 | 342,461 |
| For common | $3,269,106 | $3,270,242 |

The generating capacity of the Montana Power system now stands at 245,000 kw., 18,000 kw. having been added during the year. The year's output totaled 1,366,997,834 kw.-hr., which is approximately the same as the 1926 figure. The yearly load factor was 81.5 per cent and the company served 49,844 customers, an increase of 2,220.

Earning figures of the company for the past two years were as shown in the accompanying table.

## Utility Financing Active

During the week ended April 26 new offerings by the electric light and power companies of the country totaled approximately $58,000,000. One of the largest issues of that type brought out during the year was offered by Cities Service Company in the form of 5 per cent gold debentures, a piece of financing involving a total of $50,000,000. These securities were priced at 98 and interest to yield 5.13 per cent.

The Railway & Light Securities Company offered 4½ per cent collateral trust gold bonds to the amount of $3,000,000, the price being 94½ and interest, to yield about 4.90 per cent. These bonds, due May 1, 1953, are a direct obligation of the company, which was organized for the purpose of holding for income or sale the securities of public utility enterprises.

Six per cent cumulative preferred stock of the Iowa Power & Light Company was issued to the amount of $1,000,000 at $100 per share and accrued dividend.

The American European Securities

Company made two new offerings, one in the form of collateral trust 30-year sinking fund 5 per cent gold bonds, amounting to $2,000,000, and the other in the form of common stock of no par value, totaling 30,000 shares. The company was organized in 1925, under the laws of the State of Delaware, to take over the assets and business of the Investment Company for Electrical Enterprises in the United States, a Swiss corporation established in 1910.

Worthington Pump Elects New Directors.—E. T. Fishick and W. C. Stettenius have been elected members of the board of directors of the Worthington Pump & Machinery Corporation.

National Power & Light Increases Common Dividend. — The National Power & Light Company declared a quarterly dividend of 25 cents on the common, placing the stock on a dollar annual basis, against 80 cents previously. Initial quarterly dividend of $1.50 was also declared on the $6 preferred. The common dividend is payable June 1 to stock of record May 15 and the preferred May 1 to stock of record April 24.

## General Electric Sales Billed Down Slightly for Quarter

Sales billed by the General Electric Company for the first quarter of 1928 were $71,640,790, against $72,474,474 for the first quarter of 1927. Profit available for dividends on common, however, was $11,261,842, against $11,028,143. The comparative statement for the first quarter of the two years is given in the following table:

| | 1928 | 1927 |
|---|---|---|
| Net sales billed.......... | $71,640,790 | $72,474,474 |
| Less costs............... | 63,404,807 | 63,641,300 |
| Net income from sales.... | $8,235,982 | $8,833,173 |
| Other income, less interest paid and sundry charges | 3,669,504 | 2,838,557 |
| Profit available for dividends ............... | $11,905,487 | $11,671,731 |
| Less: Cash dividends on special stock.......... | 643,644 | 643,587 |
| Profit available for dividends on common stock | $11,261,842 | $11,028,143 |

## Utility Bonds Called in April Total $116,846,830

Among the electric light and power securities called for payment in April in advance of maturity are the following:

accrued interest on June 1, 1928, all its first mortgage sinking fund gold bonds, 6½ per cent series, due 1950, issued and outstanding.

RECENT LISTINGS.—The New York Stock Exchange has authorized the listing of 5 per cent cumulative first preferred stock of the Duquesne Light Company to the amount of $20,000,000 and additional shares of common stock of the Engineers Public Service Company—no par value— numbering 100,000. There has also been authorized the listing of not exceeding $64,530 common stock of the Federal Light & Traction Company on official notice of issuance as a stock dividend, making the total amount applied for $6,517,965 common stock. The listing has also been authorized of 115,403 additional shares of common stock without par value of the North American Company, on official notice of issuance as a stock dividend, making the total number of shares applied for to date 4,742,861 shares. The New York Stock Exchange has authorized the listing of 14,000 additional shares of class A stock of the Utilities Power and Light Corporation without par value, on official notice of issuance and payment in full, making the total amount applied for 584,000 shares of class A stock.

ILLINOIS STOCKHOLDERS AUTHORIZE NEW PREFERRED ISSUE.—At a special meeting held April 23 stockholders of the Illinois Power & Light Corporation approved the new set-up outlined in the March 24 issue of the ELECTRICAL WORLD. The plan calls for the issuance of 600,000 shares of no-par value preferred stock, proceeds from the sale of which will be used to refund the 7 per cent cumulative preferred stock now outstanding. The new stock will be callable at 110.

CALIFORNIA UTILITY INCREASES CAPITAL STOCK.—The San Diego Consolidated Gas & Electric Company, San Diego, Cal., has recently increased its capital stock from $20,000,000 to $30,000,000.

NEW YORK STATE ELECTRIC INCREASES SHARES.—The New York State Electric Corporation has filed a certificate in the office of the Secretary of State increasing the number of shares from 100,000 (no par value) to 150,000 shares (no par value).

## Cities Service Adds 50,000 New Stockholders

More than 50,000 new names have been added to the security holders' list of the Cities Service Company during the past year, according to a recent announcement made by the company. The list now totals 350,000.

## Electric Bond & Share to Issue Stock

The board of directors of the Electric Bond & Share Securities Corporation has voted to offer pro rata to the common stockholders of that corporation of record April 30 the privilege of subscribing at $80 per share for one share of its common stock for each three shares of common stock held by them, respectively. This will call for the issuance of 600,957 shares of its authorized common stock.

## Twenty per Cent in Utilities

The Metropolitan Life Insurance Company, one of the nation's largest investors, has 20 per cent of its entire bond holdings in public utility bonds. Out of a total of $990,996,000 invested in bonds, both domestic and foreign, $200,004,300 are the bonds of public utilities and almost $60,000,000 of this was added during 1927.

**MOHAWK-HUDSON CORPORATION INCREASES PREFERRED STOCK.**—At the annual meeting of the stockholders of the Mohawk-Hudson Power Corporation it was voted to increase the authorized shares of preferred stock to 500,000 from 400,000 and the authorized shares of second preferred stock from 250,000 to 500,000. One new director was elected, Frederick J. Fuller, vice-president of the Central Union Trust Company, to succeed the lates James C. Brady. Other directors were re-elected.

**ANNUAL REPORT OF G. E. EMPLOYEES' SECURITIES CORPORATION.** — The fifth annual report of the G. E. Employees' Securities Corporation shows a total of 27,147 bondholders, an increase of 1,660 over a year ago, with an average holding of approximately $1,000. In addition there are 5,000 employees of the General Electric Company who are paying for bonds on installment subscriptions. The total amount paid bondholders as interest during 1927 amounted to $1,647,500. This brings the total of all payments to bondholders, including the extra 2 per cent paid by the General Electric Company since organization of the corporation, to $6,227,975. Total assets of the corporation amount to approximately $45,000,000, more than $9,000,000 in excess of 1926. Net income from operations amounted to $1,046,845, an increase of $315,465 compared with 1926.

# More than 80,000,000,000 Kw.-Hr. Generated in 1927

AN OUTPUT of 80,205,474,000 kw.-hr. was produced by public utility power plants in the United States in 1927, according to a recent compilation of the United States Geological Survey. Of this total the output from water power amounted to 29,875,008,000 kw.-hr., or 37.2 per cent, the balance, 50,330,466,000 kw.-hr., being produced from fuel. The fuel consumption consisted of 41,888,000 tons of coal, 6,782,000 bbl. of fuel oil and 62,919,000,000 cu.ft. of natural gas. This is equivalent to 45,910,000 net tons of coal, from which there was generated 49,995,000,000 kw.-hr. at an average fuel consumption of 1.84 lb. of coal per kilowatt-hour; for the small remainder wood fuel was used, more than two-thirds of it in Oregon.

In 1919 the average consumption of coal was 3.2 lb. per kilowatt-hour, in 1926 it was 1.95. The improvement in efficiency has been steady throughout this entire period.

The leading division in the use of water power is the Pacific, where it constituted 90.1 per cent of the total; the next is the Mountain, with 86.2 per cent. The imports from Canada during the year came to 1,632,609,000 kw.-hr. and the corresponding exports to Canada were 4,868,000 kw.-hr.

The generator capacity, 25,398,385 kw. in 3,805 plants in 1927, increased to 27,690,891 kw. in 3,740 plants in January, 1928. Only plants of 100 kw. or larger are here included and only establishments generating energy are counted. The data should therefore not be confused with other compilations which also comprise smaller companies, or those engaged exclusively in resale of purchased energy.

These figures apply to all public utility power plants, including electric light and power, railways, Bureau of Reclamation and certain manufacturing plants selling energy for public utility purposes. Regional data are given in the accompanying tables. The compilation as published by the survey includes detailed data for the individual states.

# Business News and Market Conditions

## Committee Appointed to Study Sub-Standard Material

At a meeting held at the auditorium of the Consolidated Gas Company's building, New York City, on March 29 Charles L. Eidlitz, chairman of the board of governors of the Electrical Board of Trade of New York, Inc., was instructed to appoint a committee to try to crystallize the thoughts and intentions of the industry along lines which may result in controlling the manufacture, sale and use of sub-standard and hazardous materials and appliances. A report of this meeting appeared in the April 7, 1928, issue of the ELECTRICAL WORLD on page 737.

The following committee has been appointed by Mr. Eidlitz: J. C. Forsyth, chairman, New York Board of Fire Underwriters; Nicholas J. Kelly, New York City department of water supply, gas and electricity; H. R. Sargent, General Electric Company; Louis Freund, contractor; Edward C. Brown, contractor; Harry Kirkland, Society for Electrical Development; L. E. Moffatt, *Electrical Merchandising;* Frank Pattison, consulting engineer, and T. H. Joseph, contractor.

## Electrical Committee to Hold Special Meeting

A special meeting of the electrical committee of the National Fire Protection Association will be held at Atlantic City on May 3, 4 and 5, 1928, in the Chalfonte Hotel. A meeting of the correlating committee also has been called for the early morning of May 3. The annual meeting of the N.F.P.A. will begin on Monday, May 7.

The first meeting of the correlating committee was held on March 22, 23 and 24 last in accordance with the ac-

### *Value and Destination of Electrical Exports for January, 1928, Compared With Corresponding Month in 1927*

tion taken at the February, 1928, meeting of the electrical committee. The program followed by the correlating committee and which was suggested by Chairman V. H. Tousley was as follows:

1. That an editorial committee of three be appointed to prepare, and report to the meeting, wordings for requirements agreed upon in principle.

2. That any single item not agreed upon within ten minutes of discussion should be laid upon the table for discussion at the end of the meeting.

3. That only those items adopted by a two-thirds majority should be included in the correlating committee's report to the electrical committee with the recommendation that they be adopted at the special May meeting.

4. That items not so agreed upon should be referred to the electrical committee with the recommendation that they be treated as a special order of business at the February, 1929, meeting of the electrical committee.

## Productive Activity for Quarter 1 per Cent Over 1927

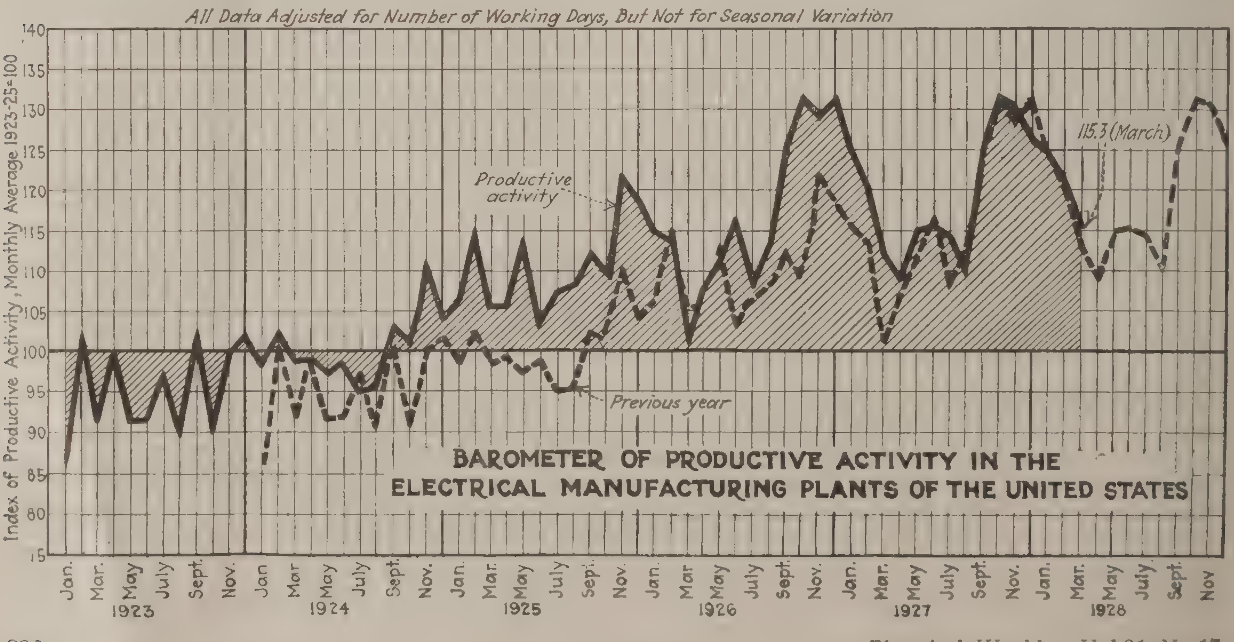
### Electrical Manufacturing Industry Following 1927 Trend, But on Slightly Higher Plane—March Rate of Operations 2.3 per Cent Over 1927

THAT the electrical manufacturing plants of the nation are operating at a slightly higher rate than the same time last year is indicated from reports on March consumption of electrical energy received by the ELECTRICAL WORLD from a large proportion of these plants. The average rate of productive operations during the first quarter of 1928 was about 1 per cent over that for the same period in 1927, but the March activity was 2.3 per cent over March last year. It would appear, therefore, that the operations of the electrical manufacturing plants during the present year are following very closely the trend witnessed during 1927, but on a slightly higher plane. The March rate of activity was 5.4 per cent below February and 12.3 per cent under October, the peak month for the past season. This reduction in activity, however, is perfectly normal in this industry. Past history would indicate that an upward turn will probably take place in April, although last year April activity was 3.4 per cent under March.

The index of activity in the electrical manufacturing industry based on consumption of electrical energy stands at 115.3 for March, as compared with 121.8 in February and 124.7 in January. Comparative indexes of productive activity referred to the average activity for the period 1923-25 as 100 and adjusted for number of working days are as follows:

| | |
|---|---|
| March, 1928 | 115.3 |
| February, 1928 | 121.8 |
| October, 1927 (peak month) | 131.3 |
| March, 1927 | 112.7 |
| Average first quarter 1928 | 120.6 |
| Average first quarter 1927 | 119.3 |

The operations of the larger electrical manufacturing companies showed a much larger drop in activities from February to March than was reported by the smaller companies. Both groups, however, are now operating at about the same rate as compared with the average rate of activity during 1923-25.



# Market Conditions

CENTRAL-STATION buying continues to be quiet with conditions better than they were earlier in the year. Industrial plants are purchasing in fair volume although the activity is not as great as it was last year. It is anticipated that the Lackawanna Railroad will place orders within the next 60 days for electrical equipment in connection with the electrification of its suburban system in northern New Jersey at a cost of about $14,000,000.

In New England industrial plant buying was outstanding. Two orders for motors and control totaled over $150,000. Power companies are active in the Eastern district, and industrial business continues at a fair rate. In the Southeast power companies are buying conservatively though a few large orders are reported. Business is quiet in St. Louis but inquiries are good. In the Middle West conditions are gradually improving. On the Pacific Coast orders have been disappointing but prospective business is excellent. An order for $250,000 worth of equipment was placed by the Washington Pulp & Paper Company.

### *Copper and Zinc Markets Stiffen*

A moderate volume of business with a firmer tendency in prices for copper and zinc is the feature of the week in the non-ferrous metal markets. More sales of copper are reported than for three weeks and since Monday there has been decidedly less tendency to shade the price of $14\frac{1}{4}$ cents asked by the primary producers. The sellers of zinc have not pressed metal on the market and were

NEW YORK METAL MARKET PRICES

| | Apr. 18, 1928 Cents per Pound | Apr. 25, 1928 Cents per Pound |
|---|---|---|
| Copper, electrolytic...... | 13.9875 | 14.00 |
| Lead, Am. S. & R. price | 6.10 | 6.10 |
| Antimony............... | 10.00 | 10.00 |
| Nickel, ingot............ | 35.00 | 35.00 |
| Zinc spots.............. | 6.10 | 6.15 |
| Tin, Straits............ | 52.50 | 52⅛ |
| Aluminum, 99 per cent... | 24.30 | 24.30 |

Base copper wire price April 25, 1928, 16 cents.

able to realize slightly higher prices for the modest tonnage traded in. Lead is steady at 6.10 cents, New York, and 6 cents, St. Louis, and tin after a slight sag is back in the neighborhood of 52⅛ cents for prompt Straits.

## *Industrial Buying Heavy in New England*

Sales of general purpose motors, control equipment and switchboards were outstanding items of interest in the electrical market in the New England district. Small motor sales mounted to over $50,000, which is slightly above the normal, with a higher trend. One order amounting to about $12,000 worth of motors was reported. Another order for complete installation of operating and control equipment for a well-known Connecticut industry totaled about $140,000.

Central-station buying is spotty. An encouraging demand for insulators and line material was recorded. Interest in arc welding is strong with orders gaining over last year. Street-lighting business is active, and one manufacturer records much activity in automatic street traffic signals, sales of which mounted to over $10,000 for the first quarter of this year. Industrially the New England district is gaining, with exceptions in a few instances.

## *Power Companies Buying in Good Volume in Southeast*

Central-station companies in the Southeast are buying conservatively, though a few large orders are reported. A company operating in the Carolinas has placed an order for 2,800 electric ranges to use in a sales campaign, and a company in Mississippi ordered motors totaling about $20,000. A company in south Georgia ordered oil engine generating equipment, amounting to $40,000, for use as a stand-by for a small hydro-electric plant. The demand for creosoted pine poles is very active and as a result deliveries are unsatisfactory. An order for $30,000 worth of oil circuit breaker equipment is in immediate prospect.

A cotton mill in Georgia bought $2,500 worth of wiring materials and $10,000 worth of motors were recently ordered. An additional order for wiring materials amounting to about $5,000 is in immediate prospect. A cotton mill in the Carolinas ordered motors amounting to $2,800 and several synchronous motor orders are being received for new ice plants in the territory, the latter orders averaging $1,000 each. Construction contracts have been let on the new building program of the Southern Railway in Atlanta and some orders for electrical materials, of which about $25,000 worth will be needed, have already been placed.

Two municipalities in Louisiana ordered "white-way" equipment amounting to $12,000 and $9,000, respectively. A club in Birmingham has placed an order for $3,000 worth of electrical cooking equipment for a completely electrified kitchen. Construction projects are as follows:

The Georgia-Florida Power Company, Valdosta, will construct 13 miles of transmission line and install two substations at Pavo and Barwick where municipal plants have been acquired. Swift & Company, Chicago, plans a cottonseed oil mill at Jacksonville, Fla., to cost $225,000. The Roberts & Grentner Properties, Inc., Miami, Fla., plans a cold storage plant to cost $300,000. The Powell Knitting Company, Spartanburg, S. C., plans an addition to cost $180,000. The South Carolina Power Company, Charleston, S. C., has acquired the municipal plant at Walterboro, S. C., and plans an addition to cost $75,000. The Diamond Ice Company, Knoxville, Tenn., will build an ice plant to cost $150,000. Lake Placid, Fla., and Danville, Va., plan ornamental lighting systems. The Virginia Electric & Power Company, Richmond, Va., plans to expend $4,000,000 for improvements throughout its territory. Of this amount $1,300,000 will be used for street railway and gas works.

## *Conditions Gradually Improving in Middle West*

While the volume of business transacted in the Middle West is not large, conditions are improving. Considerable interest is being aroused in the coming World's Fair in Chicago in 1933. The railroads are coming into the market for a considerable quantity of equipment and general purchasing of maintenance materials is heavy. The various utility companies are actively engaged in spring construction work and maintenance purchasing is particularly heavy. Among the interesting orders placed were one for labor and material to build foundations for coal handling structure, complete with appurtenances valued at $130,000; cable valued at $28,000; five 1,000 kva. transformers; six 10-ton hand operated hoists complete with appurtenances and "Mazda" lamps valued at $150,000. Jobbers sales are improving. Construction projects are as follows:

The J. W. Hoodwin Company, Chicago, will build a factory for making advertising novelties, at a cost of $100,000. The Halsom Products Company, Chicago, will build a toy manufacturing plant to cost $100,000. Kendallville, Ind., plans additions to its municipal plant, to cost $50,000. The Detroit Electric Company, Detroit, plans an operating unit on West Jefferson Street to cost $120,000. The Chevrolet Motor Car Company, Detroit, will build an addition to cost $400,000. Durant Motors, Inc., Lansing, Mich., will build additions to its plant to cost $700,000. The Northern States Power Company, Minneapolis, Minn., will make additions in its power plant at Minot, N. D., to cost $75,000. The Madison Gas & Electric Company, Madison, Wis., plans additions in its power plant at Madison, Wis., to cost $250,000. The Marshall Electric Company, Marshalltown, Iowa, will build extensions to transmission lines. The Nebraska Power Company, Omaha, Neb., will make extensions in transmission lines in the vicinity of Waterloo, Neb. Westmont, Ill., and Appleton and Neenah, Wis., plan ornamental street-lighting systems.

## *Industrial Demand Active in Eastern District*

Industrial business continues at an encouraging status in the Eastern district and sizable contracts have been placed for motors, control apparatus and accessory equipment. A leading manufacturer has secured an order from a steel tube mill in Ohio for $22,500 worth of motors. A cement company in eastern Pennsylvania also ordered nine generator units, motors and auxiliary equipment for a conveyor drive. A contract was placed by a rolling mill at Trenton, N. J., for heavy industrial equipment aggregating $168,000. Hotel interests in the metropolitan district are reported in the market for construction material. There is a marked increase in the demand for fractional-horsepower motors. The shoe manufacturing industry has been active. There is a marked decline in the call by jobbers for electric fans.

Power companies are active in the market for requirements for early delivery, particularly in connection with substation equipment. A metropolitan utility has placed an order for $25,000 worth of transformers. Other business of similar character is coming from central stations in northern New York, as well as in New Jersey. Line equipment, which has been showing a tendency to lag under a demand primarily of maintenance character, is operating under an improved call. A manufacturer of wire and cables reports business as unsatisfactory for April. May account, however, is expected to bring about a noticeable increase in orders as indicated by present inquiries. Current construction operations include the following:

The New York, New Haven & Hartford Railroad, New York, plans an electrical inspection shop on Mathews Avenue to cost $180,000. The Erie Railroad will make extensions at its shops at Port Jervis and Hornell, N. Y., and Meadville, Pa., to cost $250,000. The Wright Aeronautical Corporation, Paterson, N. J., will build plant additions to cost $2,500,000. The Public Service Electric & Gas Corporation, Newark, N. J., will build a transmission line from Metuchen to Liberty Corner, and thence through Somerset and Hunterdon Counties to Lambertville. The Otis Elevator Company will build a plant addition at Harrison, N. J., to cost $350,000. The Trenton Potteries Company, Trenton, N. J., will make plant extensions to cost $400,000. The Atlantic City Electric Company, Atlantic City, N. J., has acquired the municipal plant at Gibbstown, N. J.

England, Walton & Company, Philadelphia, will build an addition to its leather plant to cost $1,000,000. The Nice Ball Bearing Company, Philadelphia, plans an addition to cost $150,000. The Mine Safety Appliance Company, Pittsburgh, will take bids for an addition to cost $100,000. The Signal Corps, Baltimore, Md., is asking bids until May 16 for two 150-ft. steel radio towers (Circular 1). The Bureau of Yards and Docks, Navy Department, Washington, D. C., is asking bids (no closing date stated) for generating equipment for naval station in Cuba (Specification 5356). The General Purchasing Officer, Panama Canal, Washington, D. C., is asking bids until May 14 for electrical appliances, wire, cable, etc. (Panama Schedule 1874.)

### *Business Quiet with Good Inquiries in St. Louis*

Business in the St. Louis district is below the average of the previous week. Manufacturers report orders received are mainly for small motors and equipment but figures are being submitted on important inquiries to be closed in the near future. Retail dealers and jobbers experienced very satisfactory business from a steady volume of small orders for miscellaneous items, with appliances and building and line construction materials the most prominent. Construction projects are as follows:

The International Shoe Company, St. Louis, will build a canvas fabric mill at Malvern, Ark., to cost $150,000. The Beaumont Export & Import Company, Beaumont, Tex., plans a lumber mill to cost $100,000. The Chase Bag Company, Dallas, Tex., plans a plant on South Lamar Street, to cost $110,000. The Pure Oil Company, Houston, Tex., plans additions in its refinery, to cost $150,000. Nocona, Tex., plans a municipal power plant. The Central Power & Light Company, San Antonio, Tex., plans a hydro-electric plant on the Rio Frio River, to cost $250,000. Swift & Company, Chicago, plans a cold storage plant at South Dallas, Tex., to cost $150,000. The Texas-Louisiana Power Company, Fort Worth, Tex., plans a power plant near Yoakum, Tex., to cost $150,000. The United Power & Light Company, Abilene, Kan.; has secured permission for a transmission line from Chandler to Luther, Okla. The Texas Power & Light Company, Dallas, Tex., has acquired the Corsicana (Tex.) Power & Light Company, and plans transmission line extensions. Bossier City, La., and Fort Stockton, Tex., plan ornamental lighting systems.

### *April Orders Off But Inquiries Good on Pacific Coast*

April ordering on the Pacific Coast has been rather disappointing, although prospective business is excellent. Bumper crops are forecast by additions to packing plants at Concord, Santa Clara, Elmhurst and Watsonville. The state of California has announced a ten-year building program for the Sacramento State fair grounds comprising six major buildings of which the livestock building will be completed for next year. Pole orders include one carload for Woodland, two carloads for Fresno and $7,500 worth of poles and pole line material for Fallon, Nev. The government has purchased 50 miles of No. 17 copper steel wire for the forest service and has placed a contract for $125,000 covering the wiring, heating, and plumbing of the submarine base in Pearl Harbor, Hawaiian Islands. Pumping plant business is running about 30 per cent over that of last year.

The Washington Pulp & Paper Company, a subsidiary of the Zellerbach Paper Company, has let contracts for furnishing approximately $250,000 worth of turbines, motors, etc., for plants building at Port Townsend and Hoquiam, Wash. An order amounting to $15,000 also was placed by the Union Bag & Paper Company at Tacoma for a switchboard. A 10,000-hp. turbine was purchased by the Grays Harbor Railway & Light Company at Aberdeen. The Weyerhaeuser Timber Company at Longview, Wash., issued specifications and will open bids in two weeks for approximately 10,000 hp. in motors, to cost about $150,000. Construction projects are as follows:

The Atchison, Topeka & Santa Fe Railway Company, Chicago, plans an ice and car re-icing plant at Ashfork, Ariz., to cost $650,000. Johns-Manville, Inc., New York, plans a new plant at Richmond, Calif., to cost $2,500,000. The San Diego Consolidated Gas & Electric Company, San Diego, Calif., plans a steam power plant on West Broadway, to cost $435,000. The Pacific Manufacturing Company, Santa Clara, Calif., plans a woodworking plant to cost $200,000. The Coast Counties Gas & Electric Company, Santa Cruz, Calif., will build a substation at Watsonville, Calif., to cost $30,000. The Public Service Company of Colorado, Denver, will build a storage plant to cost $350,000.

The Escalante Light & Power Company, Escalante, Utah, plans a power plant to cost $65,000. The Puget Sound Power & Light Company, Seattle, Wash., will build a substation on Massachusetts Street to cost $35,000. The Washington Water Power Company, Spokane, Wash., will build a substation on South Tacoma Street, to cost $50,000. The American Fruit Growers, Inc., Yakima, Wash., will build a cold storage plant to cost $140,000. The Great Western Power Company, San Francisco, Calif., has acquired the plant and property of the Quincy Electric Light & Power Company, Quincy, Calif. Tulare, Salinas, Monrovia, Orange, Auburn, Berkeley, and Sacramento, Calif., and Montesano, Wash., plan street-lighting systems.

# Activities of the Trade

### Industrial Heat School to Be Held at Mansfield, Ohio

Plans for the 1928 National Industrial Heating School, which will be conducted this year through the courtesy of the Westinghouse Electric & Manufacturing Company at Mansfield, Ohio, have just been announced by W. H. Sammis, chairman industrial heating committee, Commercial National Section, N.E.L.A. The dates for the school, which is open to representatives of public utilities, are May 14 to 26. The course will consist of lectures and studies conducted by nationally known authorities on the subject, supplemented by inspection trips through a number of large industrial plants for first-hand observation of industrial heating operation and results. Some 225 men have taken this course in the previous schools and their companies experienced profitable results.

The only cost to central-station companies sending men to take the course is the living (averaging perhaps $7 per day) and traveling expenses of their representatives for two weeks. Those desiring to take the course should send their enrollment to W. H. Sammis, chairman industrial heating committee, N.E.L.A., care of Consumers Power Company, Jackson, Mich.

---

THE SAFETY CABLE COMPANY, division of the General Cable Corporation, 420 Lexington Avenue, New York City, announces that Merritt L. Tice, formerly connected with the Benjamin Electrical Manufacturing Company, will represent the company in the Southeastern part of the country.

THE BLACK & DECKER MANUFACTURING COMPANY, Towson, Md., manufacturer of portable electric tools and grinders, announces that its Detroit branch is now located at 11501 Woodward Avenue, with J. H. Walker as manager. The company also announces the following changes in its sales organization: H. L. Balke is with the Kansas City branch, covering the territory around Omaha, formerly covered by S. D. Shawgo; G. F. Parr is with the Buffalo office, and has taken over the territory of J. H. Hutton; G. N. McCarthy has filled the vacancy at the Buffalo office made by H. B. Austin, who has been transferred to Chicago, and J. A. Murray is working in Baltimore, taking over the accounts formerly sold by Curtiss Watts.

THE EDISON ELECTRIC APPLIANCE COMPANY, 5600 West Taylor Street, Chicago, announces a new "Hotpoint" iron known as the "Super-Automatic" iron with the heat throttle.

THE DAMPNEY COMPANY OF AMERICA, Hyde Park, Boston, announces that the sale of its "Apexior" protective coatings for power plant equipment will be handled in Iowa, Kansas, western Missouri and eastern Nebraksa by F. W. Hay & Company, with main office at 2732 Cherry Street, Kansas City, Mo., and branches in Omaha and Cedar Rapids.

THE INGERSOLL-RAND COMPANY, 11 Broadway, New York City, announces the opening of a branch office at 226 West A Street, Picher, Okla., to serve northern Oklahoma, southern Missouri and Arkansas.

THE WESTINGHOUSE LAMP COMPANY has announced a reduction in the list price of its flashlight, radio panel, and toy train incandescent "Mazda" lamps, to become effective on May 1. The reduction, amounting to 23 per cent, was made possible, according to officials of the company, by the increased demand for these types of lamps, and particularly so by lower manufacturing costs, made possible by newly developed machines.

# New Equipment Available

## Magnetic Motor Starting Switch

The "Circle T" magnetic motor starting switch rated at from 1 hp. to 15 hp. has been placed on the market by the Trumbull Electric Manufacturing Company, Plainville, Conn. In this switch a set of moving contacts is used to bridge the gap between two sets of stationary contacts. High interrupting capacity is maintained because of this contact construction. Overload and undervoltage protection is obtained by thermal relays of the inclosed type. The contacts of this switch are self-aligning and self-cleaning.

## Semi-Portable, Single-Stage Compressor Unit

A semi-portable, single-stage, double-acting, multiple-belt-driven air compressor which is completely self-contained and fully equipped has been placed on the market by the Pennsylvania Pump & Compressor Company, Easton, Pa. The motor, starter, multiple-belt drive, air receiver, air filter and automatic start and stop control are all assembled in place, forming a compact unit occupying the minimum of floor space. The air cylinder and all working parts are automatically lubricated. The compressor is equipped with Pennsylvania air-cushioned valves and contains all other features which are built into the company's standard compressors. The unit is equipped with a 10-hp. high-torque motor operating the compressor at 400 r.p.m. The unit has automatic pressure control between 85 lb. and 125 lb., is 6 ft. 8 in. long by 2 ft. 4 in. wide and weighs 1,380 lb. Another unit also is built in a two-stage type for pressures from 125 lb. to 250 lb.

Solenoid Brakes.—A complete new line of solenoid brakes is now being offered by the General Electric Company. The line, bearing the designation CR-9516, includes brakes for operation on alternating and direct current, and involves in its construction the use of a spring-setting device. The company claims simplicity as the main feature of the new line. The brakes are especially designed for severe service in connection with mill, crane and hoist motors. The manufacturer claims smooth operation for making quick stops in either direction of rotation, with a dependable holding value. The brake mechanism is held in the "off" position by a coil and plunger; when power is applied to the motor, the coil is energized and the brake is released, and, when the power is shut off, the spring-setting device forces the mechanism into the closed or braking position. Both alternating- and direct-current brakes use the same brake mechanism and frame, the solenoids being interchangeable. The solenoid assembly may be quickly removed from the brake mechanism by taking out four bolts, lever or brake adjustments remaining undisturbed. The coil only may be removed, if desired, from the larger sizes.

## Portable Pole Saw

The Wolf portable timber-sawing machine for use in pole yards for the roofing of poles, the cutting of anchor blocks, the cutting up of old poles for fire wood and other operations has been placed on the market by the Reed-Prentice Corporation, Worcester, Mass. The company claims that the Wolf saw operated by two men will perform the work of at least eight men with hand cross-cut saws, and any operation ordinarily handled with cross-cut saws can be speeded up with the Wolf saw. The machine is available in alternating-current, direct-current and compressed-air drive and has a capacity up to timbers 24 in. in diameter.

## Air Filter

A unit type air filter, for cleaning air used in cooling large motors, compressed air and similar purposes, using a blanket of cellulose material as the dirt-collecting medium, has been developed by the National Air Filter Company, Chicago. The new material, developed by the Kimberly-Clark company especially for the new filter, consists of a mat of many layers of very fine cellulose fibers. It will be known commercially as "Airmat." In a series of experimental tests the manufacturer states that he found the filter showed a surprisingly high efficiency in stripping the air passed through it, not only of the most minute particles of solid matter but of all particles of oil and oily soot. The material has a very high absorptive capacity for liquids.

A single unit consists of a sheet metal box 12 in. high, 24 in. wide and 24 in. long with a filtering capacity of 1,000 cu.ft. of air per minute. These units can be used singly or placed in multiple installations of any capacity, much after the fashion of sectional bookcases. The filtering material, resembling a very light fluffy white blanket, is carried between two frames of coarse wire screen hinged together on one side and opening out like a book. These frames are the proper size to receive a single sheet of the "Airmat," 24 in. square. Each unit contains four such frames, which form a set of staggered partitions being placed in cross-section like a letter W so that 16 sq.ft. of filter surface is contained in each individual unit. A simple spring clip holds the frames in position and they may be easily removed from the unit, opened up and a fresh blanket of "Airmat" inserted in a few seconds time without disturbing the unit itself.

## Recorder Controller

A new recorder and contacting controller which combines in one case the features of a recorder and a thermometer controller is being marketed by the Bristol Company, Waterbury, Conn. The equipment is a single pen recording system with controller system and scale mounted directly above it. The recording pen and moving contact of the controller are each actuated by separate pressure elements which are exactly alike in construction. These elements are connected through one capillary tube to the sensitive bulb, and arranged in this way the record is not impaired by the retarding effect of the controller. Also the recorder draws a true record both above and below the control point.

The recorder controller is arranged for a contact capacity of 1,000 watts by equipping it with self-contained automatic switches. To use the instrument it is only necessary to set the control to the desired temperature by moving an index pointer over a scale to the exact degree to be controlled. This index pointer is very long and it is thus possible to adjust it accurately and easily. The large current-carrying capacity of this controller makes it possible to adapt the instrument to many control applications without the use of relays.

Highway Lighting Unit.—A lighting unit designed especially for the illumination of highways has been placed on the market by the General Electric Company. The new unit is said to be of very simple construction and the light is diffused entirely by means of the combination glass globe and refractor which incloses the electric lamp. It may be mounted on standard poles, and does not require installation at excessive heights. Although particularly designed for highway lighting, it may be used in residential sections. The unit is designed for spacing at intervals of approximately 250 ft., and standard poles 25 ft. in height, or even less, may be used for mounting. The usual variety of types of casing and reflector will be available with these units, and several types and lengths of bracket can also be used.

Current Transformer.—A line of dry type current transformers, known as the type LD, has been placed on the market by the Packard Electric Company, Warren, Ohio. They have been developed especially for switchboard work for controlling relays, circuit breakers, etc., and where accuracy is not of prime importance, and are recommended for all usual light-duty work, such as supplying an ammeter, single watt-hour meter or for relay work where the burden does not exceed 25 va. Secondary binding posts are provided. The company also has revamped its K line of dry type current transformers, which are intended for accurate metering service.

# Electrical Patents

*Announced by U. S. Patent Office*

(Issued April 10, 1928)

1,665,200. Cord Holder for Vacuum Cleaners, Lamps, and the Like; H. O. Briggs, Minneapolis, Minn. App. filed April 9, 1925.

1,665,219. Heating Element for Electric Irons; W. A. Rankin, Rochester, N. Y. App. filed May 19, 1923.

1,665,223. Circuit Breaker; F. W. Roller, East Orange, N. J. App. filed Oct. 24, 1924. Trip free type.

1,665,226. Magnetic Chuck; F. L. Simmons, Woonsocket, R. I. App. filed Jan. 10, 1927.

1,665,291. Operating Gear of Electric Switches; A. Allan, North Shields, and H. W. Clothier, Walls-End-On-Tyne, England. App. filed Jan. 21, 1926. Oil-break switchgear in which the main oil-break switch with its tank can be removed entirely from the rest of the gear and if desired replaced by another similar oil switch and tank.

1,665,304. Short Circuiting Device for Electric Motors; H. L. Johnston and M. K. Akers, Troy, Ohio. App. filed March 23, 1925.

1,665,313. Protective Device for Three-Phase Alternating-Current Units; J. D. Lewis, Yonkers, N. Y. App. filed April 27, 1923.

1,665,325. Electrical Network and Its Operation; E. Peterson, New York, N. Y. App. filed March 18, 1926.

1,665,341. Thermostat; V. A. Boker, Minneapolis, Minn. App. filed April 2, 1925. Adapted for controlling the heating of the crucible of type setting machines.

1,665,347. Rail Bond; E. M. Deems, Forest Hills, N. Y. App. filed Oct. 15, 1925.

1,665,348. Electrical Water Heater; H. E. Dineson, Bridgeport, Conn. App. filed June 11, 1926.

1,665,367. Electric Heater; W. S. Johnson and J. W. Sheffer, Berwick, Pa. App. filed March 25, 1921.

1,665,381. Automatic Fire Alarm; J. Siddall, Arlington, and W. H. Siddall, Kearny, N. J. App. filed Nov. 10, 1921.

1,665,446. Fuse Clip; N. J. Conrad, Wilmette, Ill. App. filed May 25, 1925. For high-voltage fuse.

1,665,472. Electrical Hair Curler; A. H. Opperman, Indianapolis, Ind. App. filed April 25, 1925.

1,665,484. Device for Application to the Openings of Outlet Boxes and the Like; R. D. Thompson, Toledo, Ohio. App. filed Oct. 19, 1923.

1,665,495 Electric Socket; E. H. Freeman, Trenton, N. J. App. filed July 10, 1926.

1,665,510. Cord Guide; A. S. Spidel, Brewster, Ohio. App. filed Oct. 18, 1926. Cord guide members for the caps of separable attachment plugs.

1,665,528. Electric Fuse; H. T. Bussmann, St. Louis, Mo. App. filed March 20, 1922. Renewable ferrule contact type.

1,665,529. Quick-Make and Quick-Break Switch; F. LeG. Bryant, Johnson City, N. Y. App. filed March 10, 1927.

1,665,550. Contact Holder; J. T. Janette, Chicago, Ill. App. filed March 30, 1925. For holding contacts or brushes adapted for various purposes.

1,665,560. Variable Traffic Signal; R. O. Nelson, Portland, Ore. App. filed May 16, 1925. Automatic signal device for the intersection of a main or arterial highway and a cross road.

1,665,562. Starter for Electric Motors; W. C. O'Brien, Baltimore, Md. App. filed Nov. 4, 1924.

1,665,592. Crossing Signal; J. W. Kennedy, Canton, Ohio. App. filed Aug. 13, 1923.

1,665,603. Storage Battery; P. E. Norris, Wilkinsburg, Pa. App. filed May 26, 1924.

1,665,604. Storage-Battery Separator; P. E. Norris and H. H. Aldrich, Wilkinsburg, Pa. App. filed Oct. 1, 1924.

1,665,613. Coupling Device for Rotatable Elements; H. L. Tanner, Brooklyn, N. Y. App. filed June 11, 1920.

1,665,619. Apparatus for Waving Hair; C. A. Ackley, New York, N. Y. App. filed March 25, 1926.

1,665,622. Calling Device; L. L. E. Chauveau, Paris, France. App. filed Feb. 23, 1922. Selective.

1,665,629. Bootleg; F. C. Lavarack, Montclair, and W. H. B. Lavarack, Norwood Borough, N. J. App. filed June 3, 1925. As used in railway signalling.

1,665,662. Electromagnetic Detecting Device; C. E. Godkin, Hayward, Calif. App. filed Dec. 15, 1925. For use in detecting oil.

1,665,677. Alarm Device; W. C. Roe, New York, N. Y. App. filed Jan. 10, 1923. For burglar alarm systems.

1,665,691. Two-Voltage Direct-Current Generator; L. Dreyfus, Vasteras, Sweden. App. filed Feb. 23, 1927. Intended to operate in parallel with a storage battery.

1,665,703. Portable Electric Lamp; J. Kernes, Chicago, Ill. App. filed Nov. 8, 1926.

1,665,735. Bread Toaster; T. C. Forbes, Hopkins, Minn. App. filed Jan. 5, 1927. Automatic.

1,665,737. Automatic Switching-Cord Reel; J. J. Gough, Chicago, Ill. App. filed Nov. 4, 1925.

1,665,742. Induction Motor; F. S. Kingston, Warren, Ohio. App. filed April 28, 1927. Single phase induction motor employing the split phase method of starting.

1,665,746. Curling-Iron Heater; H. G. Levy, San Francisco, Calif. App. filed March 7, 1924.

1,665,768. Electric Iron; G. Browning, Wilmette, Ill. App. filed Aug. 15, 1925.

1,665,772. Storage-Battery Construction; C. C. Carpenter, Niagara Falls, N. Y. App. filed Feb. 9, 1918.

1,665,792. Electric Cigar Lighter; G. Parker, Meriden, Conn. App. filed April 8, 1926.

1,665,793. Automatic Electric Steam Boiler; O. A. Sandborgh, Stockholm, Sweden. App. filed Aug. 29, 1921.

1,665,799. Incandescent Lamp; A. B. Smith, South Brownsville, Pa. App. filed Oct. 28, 1925. Filament supporting stem equipped with suitable reflective material in order to augment the volume of the light ray.

1,665,802. Detachable Electric Fixture; W. Symmes, San Francisco, Calif. App. filed Nov. 8, 1921.

1,665,841. Electric Cut-Out; G. R. Brown, Bridgeport, Conn. App. filed Sept. 17, 1925. Plug type.

1,665,845. Antisludging Means for Oil; D. C. Cox, Soldier Summit, Utah. App. filed Sept. 28, 1926.

1,665,851. Electric Butt-Welded Tubing and Method of Making the Same; J. W. Harris, Washington, D. C. App. filed Sept. 26, 1924.

1,665,852. Regulating System; M. Herklotz, Berlin, Germany. App. filed Feb. 27, 1926. For controlling a characteristic of the output of an alternating-current generator in which the characteristic, which may be the voltage, current, power, power factor, etc., is controlled by varying the excitation of an exciter.

1,665,854. Alternating-Current Device; B. E. Lenehan, Wilkinsburg, Pa. App. filed Dec. 15, 1924. Means for readily adapting standard wattmeters for operation as reactive-volt-ampere meters.

1,665,857. Electrical Transmission System; J. C. Needham, London, England. App. filed May 26, 1920. By means of which the speed of a moving body can be readily ascertained from a distance or variations in speed can be employed to transmit orders.

1,665,858. Circuit Interrupter; W. L. Newmeyer, Wilkinsburg, Pa. App. filed July 11, 1924. Of the latching type.

1,665,861. Electric Heater; M. K. Purdy, Stroudsburg, and W. H. Reagle, Tobyhanna, Pa. App. filed Aug. 31, 1927.

1,665,869. Electric Welding; J. M. Weed, Scotia, N. Y. App. filed May 18, 1925. Arc welding system.

1,665,890. Synchronous Motor Specially for Driving Clocks; R. Michl, Kosice, Czechoslovakia. App. filed June 10, 1925.

1,665,893. System of Distribution; D. C. Prince, Schenectady, N. Y. App. filed Sept. 23, 1924.

1,665,901. Speed-Regulator System; J. H. Ashbaugh, Pittsburgh, Pa. App. filed Sept. 26, 1925.

1,665,917. Regulator System; R. D. Evans, Pittsburgh, Pa. App. filed April 12, 1921. Which will accurately function on either a balanced or an unbalanced electrical system.

1,665,918. Compensated Voltage Regulator System; R. D. Evans and H. K. Sels, Pittsburgh, Pa. App. filed March 15, 1923.

1,665,939. Regulator System; S. A. Staege, Pittsburgh, Pa. App. filed April 15, 1926. Rotary contactor type regulator system.

1,665,941. Electric Heater; A. E. M. Van Der Meersch, Chelsea, London, England. App. filed Dec. 8, 1926.

1,665,949. Water Heater; J. G. Chalmers and B. C. Salamis, Montreal, Quebec, Canada. App. filed Aug. 27, 1926.

1,665,956. Fire Alarm; S. Giangrasso, Portland, Me. App. filed Aug. 28, 1926. Of the audible signal type.

1,665,962. Storage-Battery Plate and Method of Producing Same; C. W. Jenner, New Westminster, B. C., Can. App. filed June 2, 1927.

1,665,987. Pilot Light; J. T. Smith, San Francisco, Calif. App. filed June 28, 1926. For use with heating equipment such as flat-irons.

1,666,007. Separator and Method of Making the Same; W. S. Gould, New York, N. Y. App. filed Oct. 23, 1923.

1,666,026. Process of Welding; R. Applegate, Cleveland, Ohio. App. filed Oct. 10, 1921. By the electric arc involving the use of a degasifying substance.

1,666,041. Traffic Signal; F. Buchanan, Syracuse, N. Y. App. filed Sept. 24, 1924.

# New Trade Literature

**CONDUIT FITTINGS FOR RAILWAY MAIL CARS.**—The Crouse-Hinds Company, Syracuse, N. Y., has issued bulletin No. 2112, entitled "Railway Mail Car Lighting and Fan Installations." The bulletin describes and illustrates the various types of fixtures, condulets and switches for railway mail car lighting and fan installations.

SWITCHING AND OUTDOOR STATION EQUIPMENT.—The General Electric Company, Schenectady, N. Y., has issued bulletin GEA-966, covering its indoor metal-clad switching equipment. The company also is distributing bulletin GEA-899, describing and illustrating its types HD-1 and HD-2 disconnecting switches for outdoor station equipment.

INSULATORS AND TRANSMISSION LINE HARDWARE.—Catalog No. 4 issued by the Lapp Insulator Company, Inc., LeRoy, N. Y., describes its vacuum process high-voltage porcelain insulators, its special high-voltage porcelain designs and its transmission line hardware and appliances. The catalog is well illustrated and contains several Lapp factory views. Porcelain processes are described and compared with the Lapp vacuum process and the Lapp clay-mixing process. A chapter also is devoted to Lapp standard practices. The various types of insulators, bushings, etc., are fully described and a line drawing gives all the dimensions. Attention is called to the Lapp method of packing.

ELECTRIC EQUIPMENT. — Bulletin GEA-884 issued by the General Electric Company, Schenectady, N. Y., covers its direct-current induction and synchronous motors and control particularly adapted to building and flat-glass manufacture. Illustrations are given showing the application of the motors to air compressors in a glass plant.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered, further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number:

An agency is desired in Hamburg, Germany (No. 30,832), for electrical advertising novelties and household electrical appliances, including refrigerators and washing machines.

An agency is desired in Santo Domingo, Dominican Republic (No. 30,795), for electromedical apparatus.

An agency is desired in Bogota, Colombia (No. 30,796), for high-grade flashlights.

An agency is desired in Prague, Czechoslovakia (No. 30,833), for household electrical accessories, including dishwashers.

Purchase is desired in Shanghai, China (No. 30,791), of lighting switches and receptacles.

An agency is desired in Vienna, Austria (No. 30,793), for electric household refrigerators.

An agency is desired in Sheffield, England (No. 30,797), for electric household refrigerators and units.

An extensive hydro-electric project involving $30,000,000 is planned in British Columbia, Canada (No. 274,934).

## *Boulder Dam and the Congressional Situation*

DEBATE on the Boulder Canyon bill has been in full swing in the Senate, but the measure will soon have to make way for the tax bill and possibly for action on the expected veto of the flood-control bill. As a matter of fact its proponents fear its defeat and are prepared to compromise on a low dam at Boulder Canyon with a foundation capable of sustaining ultimately a structure of the height sought in the present Swing-Johnson bill. However, in view of the opposition to the measure and to the absence of any treaty between the states in the Colorado River basin apportioning the water, it is problematical whether any action will be taken at this session of Congress.

Fortunately, time has sufficed to shed light on many of the questionable features of the proposed measure, on the engineering aspects of the project, on the selfishness of California—and especially Los Angeles—and on the rights of the other states. The fact has also been accentuated that every one wishes to protect the Imperial Valley, although the menace is not so great as the California senators would have people believe. Besides, since Dwight Morrow has been Ambassador to Mexico there is a general change of sentiment toward the Southern republic and the administration is not now seeking clubs like the Boulder Canyon Dam to hold over Mexico's head. Best of all, however, is the growing resentment against the government engaging in business under any pretext, and it is that sentiment—one the politicians are beginning to discern—which will play an important part in keeping Congress within bounds.

* * * *

## *Worcester Rate Adjustment a Sensible Step*

PENDING final determination in the federal court of the Worcester case against the Massachusetts Department of Public Utilities, the contestants have agreed on a six-cent rate. The injunction against the commission was modified in the District Court at Boston to permit the new rate to become effective, and domestic users of electricity in Worcester will receive the benefit of the reduced rate at once. Both the commission and the utility company are to be commended on such a sensible arrangement.

From the viewpoint of regulation a 15 per cent reduction in the Worcester rate is a victory for the Massachusetts Department of Public Utilities. To be sure, 15 per cent is not so drastic a cut as 30 per cent; but a bird in the hand is worth two in the bush. The Worcester Electric Light Company would undoubtedly suffer a loss in income were the 30 per cent reduction to be applied at once. As it is, the courts may sustain the commission, in which case the full reduction will become effective; but the litigation might consume years. Meanwhile a voluntary cut of 15 per cent is granted, and by the time the case is settled—presuming that the decision goes against the utility, which is not at all certain — the company will have adjusted itself to the change. Regardless of the final outcome, however, the present reduction will stand, and if after a reasonable trial it is shown to be highly remunerative, we feel certain that the Worcester Electric Light Company will voluntarily grant to the Massachusetts commission what the latter may not be able to wrest from it by law. Such, certainly, would be a reasonable and sensible disposition of the case and one in entire harmony with the best public policy.

* * * *

## *Is the Federal Trade Commission Getting Anywhere?*

WHEN the public utility companies of the country were by action of the United States Senate ordered to be investigated by the Federal Trade Commission, the supposition was that the Federal Trade Commission, following its usual custom, would make a thorough investigation and report its findings in due season. That, subsequent developments have shown, was a delusion. The *ex parte* hearings being conducted in Washington are a joy to the tabloid and radical press, whose staffs crowd the hearing room and mull over every exhibit and piece of evidence, seeking sensation and scandal. Moreover, either by coincidence or by careful planning, some of the testimony sought relates to Boulder Canyon, which is now being debated in the Senate. If the proponents of that measure can get any help from the testimony before the Federal Trade Commission, they are welcome to it, for apparently they will need all the help they can muster and even then not succeed in getting their measure passed.

Touching the basic functions of the electric light and power industry—that is, the technique and economy of its service—there is not a word in the record, nor apparently, for obvious reasons, will much be sought. Along these lines the industry is well-nigh invulnerable, and it is because of that that municipal plants are losing ground and that the United States excels electrically. From a public relations angle the industry has much to learn, and it is fortunate for it that the product itself so far excels the sales argument made for it. Were this not so, the critics and defamers of the industry might be able to show some progress; but the economic performance of the industry is a rock against which they have learned from bitter experience that it is useless to dash their heads. For that reason they concentrate on and magnify propaganda, little realizing that a pound of fact will outweigh a ton of propaganda and that it is the facts of the electric light and power industry, and not the propaganda, that have made it so successful. We had hoped the Federal Trade Commission would bring these points out, and it may be that eventually it will. So far, however, it has merely reported some spicy gossip and old women's tales.

* * * *

## *Flexibility in Standardization*

THE American Engineering Standards Committee has changed its procedure in order to speed up standardization work. A sectional committee may now be autonomous; a proprietary standard is recognized and also the right of the proprietary organization to revise this standard, and a third change permits of making a standard by the action of a general conference of interested parties. Flexibility is provided in standards making, so that a quick procedure can be followed for any standard at issue.

Comments on the new procedure will be pro and con. Some of the member societies may object to the non-use of the sponsor in all cases of standards making, and there may be disputes as to jurisdiction or the method of making a standard. But only selfish interest can wreck the new plan. It is a great step in advance toward the national standardization plan advocated by the ELECTRICAL WORLD. It deserves the support of the electrical industry and a thorough trial.

## *The Key to the Great Power and Industrial Heating Load*

IT IS interesting and fortunate that the development of the further markets for electric power and electric heat in the industrial field both call for the same general approach on the part of the sales departments of the power companies. In each case the major consideration is the analysis of the diverse production problems of the many types of manufacturers to whom these applications of electric service offer opportunities to reduce costs, increase output or improve the quality of the product. Two kinds of service are offered, but for both the first step is to study the production processes of industry.

The further building of both power and industrial heating load is essentially a selling job, and it requires the same kind of man power. It calls for technically trained salesmen who can go into factories and be helpful, because they understand the mental attitude of the factory man and can sense his troubles, talk his language and win his confidence and co-operation. For electric motors and electric furnaces are not purchased save as they give promise—nay, conviction—of resulting economies through improved control, saving of space, elimination of labor, faster speed, reduction of waste or some other desired advantage. The first prime qualification of the power company's engineer, therefore, is his ability to think as a practical factory man.

The basic resource for such work is experience data—information on the conditions surrounding the various types of factories, their peculiar problems and case records that prove the value of electric power or heat. The power companies need a generous fund of such guidance well organized for study and for use. With it the utility man himself may have a practical competence in specifying the smaller sizes of motors and the simpler forms of heat equipment. But for the more intricate installations he must have recourse to experienced utility engineer salesmen and to the manufacturer's specialized application engineers. A poorly sold job is a boomerang where further business is concerned.

It is roughly estimated that but half the power used by industry is now purchased from central-station systems and that the industrial heating load will some day exceed the motor load in size. It is worth working for—and now. But, first of all, it must be made a matter of policy with every company to provide and sustain the man power to develop this waiting business. Here is the key to this great market.

## *Scholarship Brings Dividends*

BUSINESS success in the telephone industry depends largely on scholarship. Walter S. Gifford, president of the American Telephone & Telegraph Company, so declares in a recent article in *Harper's Magazine.* Records of 4,125 graduates from 104 colleges were studied carefully and showed that 498 men who had been graduated in the first tenth of their respective classes began to forge ahead of their fellow graduates after about five years of employment by the Bell system. The advantage continued to exist and after twenty-five years of employment these men advanced very rapidly. According to these records, men from the first tenth in college have four times the chances of those from the lowest third to stand in the highest-tenth salary group.

The trend toward the operation of business establishments by hired managers places a premium upon mentality and knowledge. The robust athlete with his 'varsity letter must add to it a Sigma Xi or a Phi Beta Kappa key if he expects to be a leader of his business associates.

* * * *

## *New Light on Conduction*

ELECTRICITY is thought to be granular in structure, and electric conduction is said to be either electronic or ionic in solids, liquids and gases. Electronic conduction occurs in copper wire, for example, and is not associated with the transfer of matter, but in ionic conduction electricity is associated intimately with the transfer of matter. There is no order in the matter, for both types of conduction occur in liquids, solids and gases. Nor does either theory of conduction afford us a conception of what electricity is as a physical entity.

We have become accustomed to using these theories to develop laws which engineers use in practical calculations. One of these laws, intimately related to the theory of electronic conduction, states that resistance will become infinite in conductors when the temperature of the material drops to absolute zero. Recent experiments with liquefied helium by Kammerlingh-Onnes give data which prove the exact opposite. The conductivity of certain metals becomes infinite instead of zero at absolute zero. Instead of resistance increasing as the temperature decreases, the opposite effect occurs, and in certain metals a sudden and very rapid decrease in resistance occurs at a definite temperature. Mercury, tin, lead, thallium and their alloys show this phenomenon and have virtually zero resistance at absolute zero. Why this phenomenon occurs nobody knows, nor does it seem to have any practical importance to engineers. But no one can predict the future, and this phenomenon, recent research work on the effect of purity on conductivity, other recent researches which seem to indicate that magnetism is caused by electronic currents—all these have an interrelation which will be found by some research worker.

Practical applications always follow hard on new knowledge, and the recent researches at least permit engineers to discard another so-called law in electrical engineering. Fortunately Ohm's law seems able to stand the scrutiny of modern experimenters.

## *Capitalization and Regulation*

A SECOND refusal by the Public Service Commission of Maryland to approve the purchase of four small light and power properties in that state by a Chicago holding company has followed a rehearing necessitated by a court decision that disapproval could not be based merely on the commission's opinion that no benefit to the public was involved in the sought-for transfer. A utility sale, the court pointed out, does not have to be shown to be of positive benefit to the public; it is enough that it be not detrimental to it. It may easily be that the public has nothing to gain by the sale of Company A to Company B. But if the public loses nothing, its interest is not affected and the commission should not interfere in what then has the character of a private negotiation.

Accepting this dictum as in duty bound, the Maryland commission again dismissed the petition, this time stigmatizing the proposed sale as "detrimental" to the public interest and thus substituting a positive for a negative reason to explain its action. Its real ground of objection was that the sum to be paid was far in excess of the reproduction cost arrived at by the commission engineers. It thus refused to indorse the principle that since such capital expenditures do not influence the rate base they can be approved, even when extravagant, without injury to customers. In view of the inflated prices often paid by expanding companies for competing, obstructive or "logically belonging" plants—sometimes to the enrichment of municipalities, which thus occasionally vindicate as a temporary expedient the policy of public ownership in a way the original proponents little meant—it will be interesting to see whether the Maryland commission's stand will be maintained and whether it will be followed by other commissions.

## *Making Research Developments Available to Industry*

REDUCING the time lag between the discoveries of pure scientific research and their application in industry is directly dependent not only on the growth of fundamental research resources, but also on adequate industrial research laboratories to apply the discoveries. The smaller the time lag, the more prosperous the industry and the nation. Pure scientific research has developed theories which at the time of discovery have appeared to be little more than interesting curiosities. At a later date industrial research laboratories, using these theories as a basis, have developed a means of applying them to industry so that finally they become an every-day necessity. In this way our national wealth is increased.

When Michael Faraday in 1831 discovered the principle of electromagnetic induction, he had no definite idea concerning any use to which it could be put, although he expressed his confidence in its ultimate practical application. When asked by the Prime Minister of his country as to its use, he replied: "My Lord, some day you may tax it." Events have proved to a degree undreamed of even by Faraday how true his words were. The discovery some months ago that a single copper crystal of large size had a conductivity 13 per cent greater than ordinary copper wire with its numerous crystals arranged in all directions may some day be put to work through the medium of our industrial research laboratories.

It is significant that the industries which have the best established industrial research laboratories are built on fundamental scientific research. The industrial research laboratory has played a major part in the development of the electrical industry. High-pressure and large-capacity steam generating units have been made possible only by continued research work. As one manufacturer expressed it: "Research has sold itself on the basis of dividends on every dollar spent in studying problems, and the return has more than justified it." Further development of our resources for industrial research is fraught with possibilities beyond our ken.

* * * *

## *Chemical Applications of Electricity*

RESEARCH workers persist in their efforts to generate electricity by chemical action, but only primary and storage cells of relatively low capacity have resulted from their efforts. Nothing yet discovered gives promise of energy production on a commercial scale by the use of chemical reactions. At the Bridgeport meeting of the American Electrochemical Society this topic was discussed at length. Papers outlined many improvements in primary and storage batteries, but the ingredients used fifty years ago still persist in the modern devices. Greater purity in materials, better manufacture and slight improvements obtained by adding small amounts of other material make the modern cells better than those of the days of Le Clanché, but no one has been able to find basic constituents superior to those discovered in the early days.

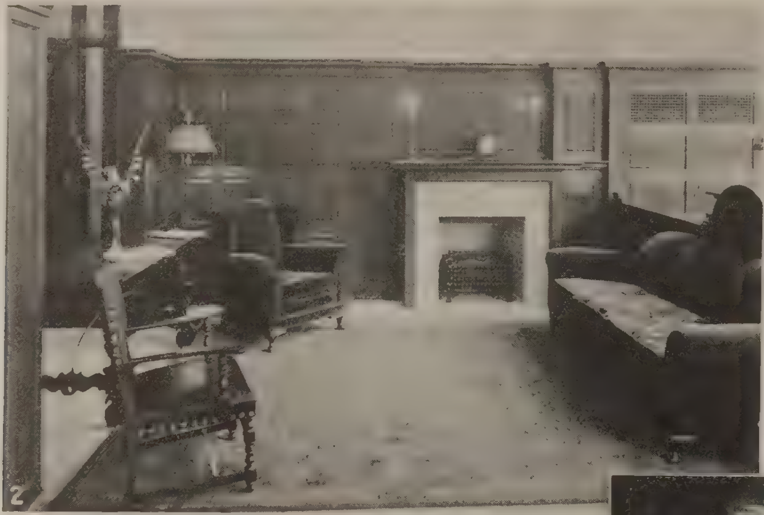
Great advances, however, have been made in the applications of electricity to chemistry and metallurgy. Electrochemical, electrothermic and catalytic effects have been introduced to improve processes and to make new products. Chromium plating is a new and very valuable application; hydrochloric and nitric acids are produced by direct distillation, using the acid itself as a resistor heater; the induction furnace for melting brass and silver has been welcomed: the arc and resistor furnaces have improved processes and products in ferrous and non-ferrous melting and treating.

It is in these directions that the greatest advances are now being made. These applications have resulted in marked economies, improved products and new products, and yet only the surface of possibilities has been scratched. Engineers would do well to keep abreast of the notable developments brought about by the electrochemists and electrometallurgists. They are makers of new industries, and their tools are electric.

# *Public Relations Aided by Design of Utility Office Building*

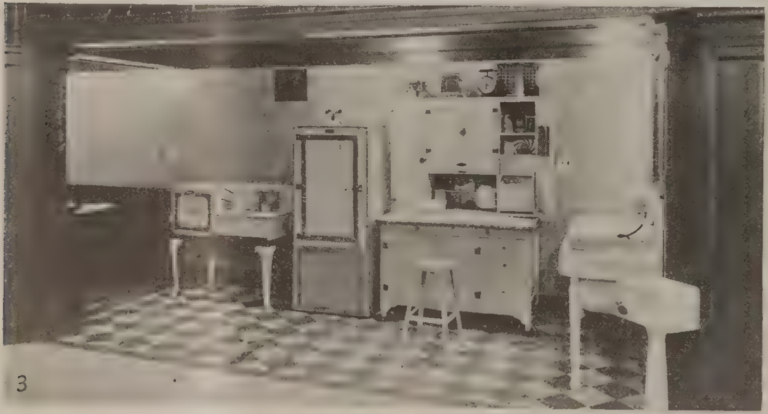
1

*Electric shop, with lamp department, cashiers' counter and sales department at rear*



2

*"Meet Me" corner, for customers' convenience near entrance of electric shop*



3

*Model kitchen and breakfast nook in street floor alcove*

4

*Night view of company's new home*

ONE OF the most beautifully appointed utility office buildings in the Northeast was thrown open to the public recently by the Public Service Company of New Hampshire, at Manchester. With a finely equipped street and mezzanine-floor electric shop, a heavy-duty appliance department in the basement, executive offices and auditorium on the upper floors, the new headquarters combines hospitality to customers with modern display methods.

# Baltimore's New Station*

### One boiler used per turbine. Low voltage auxiliaries. Automatic equipment employed. Descriptive features at Gould Street plant

THE new Gould Street plant of the Consolidated Gas, Electric Light & Power Company, which began operation in January, 1927, is located in the city of Baltimore on the Patapsco River, an arm of the Chesapeake Bay. The new station has one 36,000-kw. unit operating and a second duplicate unit which will begin operation next month. The plant is designed for four 36,000-kw. units, a total of 144,000 kw. at 60 cycles. The energy is distributed by underground cable at 13,200 volts without transformation. The plot measures 405 ft. x 635 ft. and is of sufficient size to supply load growth for perhaps ten years.

## Coal-Handling Facilities

Coal is unloaded from barges by an electrically operated tower with Mead Morrison equipment and a 2-ton bucket, the present tower having an all-day capacity of 165 tons per hour. The future twin tower will increase the capacity to 300 tons per hour. The coal from the tower hopper passes through a Bradford breaker and thence by belt conveyor to yard storage or coal preparation building.

All of the conveyors are equipped with 36-in. rubber belts and have a capacity of 336 tons per hour. There is no speed adjustment on any of the belts; the ribbon principle is used, the rate of feed or thickness of ribbon of coal is regulated by the apron feeder which delivers coal to the Bradford breaker. At the present time coal is being stocked out and reclaimed by a gasoline-engine-driven, crawler crane, equipped with a 1-yd. grab bucket. The capacity of this rig is about 60 tons per hour. When the third generating unit is installed it will be necessary to purchase a traveling bridge.

The machinery in the coal preparation house for preparing and transporting the coal comprises two 20-ton Raymond roller mills, each with a separate exhauster and circulating system and steam air heater; two transport pumps, each having a nominal rate of capacity of 40 tons per hour, and two 735-cu.ft. motor-driven air compressors. The original installation included steam driers, but these have been replaced by the system of drying in the mill. Air from a tubular air heater using steam at boiler pressure is blown into the circulating air as it enters the mill, providing hot, dry air to absorb moisture from the coal in the mill. Sufficient air is bled off from the top of the cyclone to discharge the moisture picked up and keep the humidity of the air in the circulating system below the dew point. This air bled off is replaced by heated air coming from the air heater, which is mixed with the recirculating air before it enters the mill. The cyclones in which the air and coal are separated discharge the coal into the hoppers above the coal transport pumps. The air drawn off from the circulating system passes through a concentrator, in which the heavier solids are removed, and from there it passes through a washer.

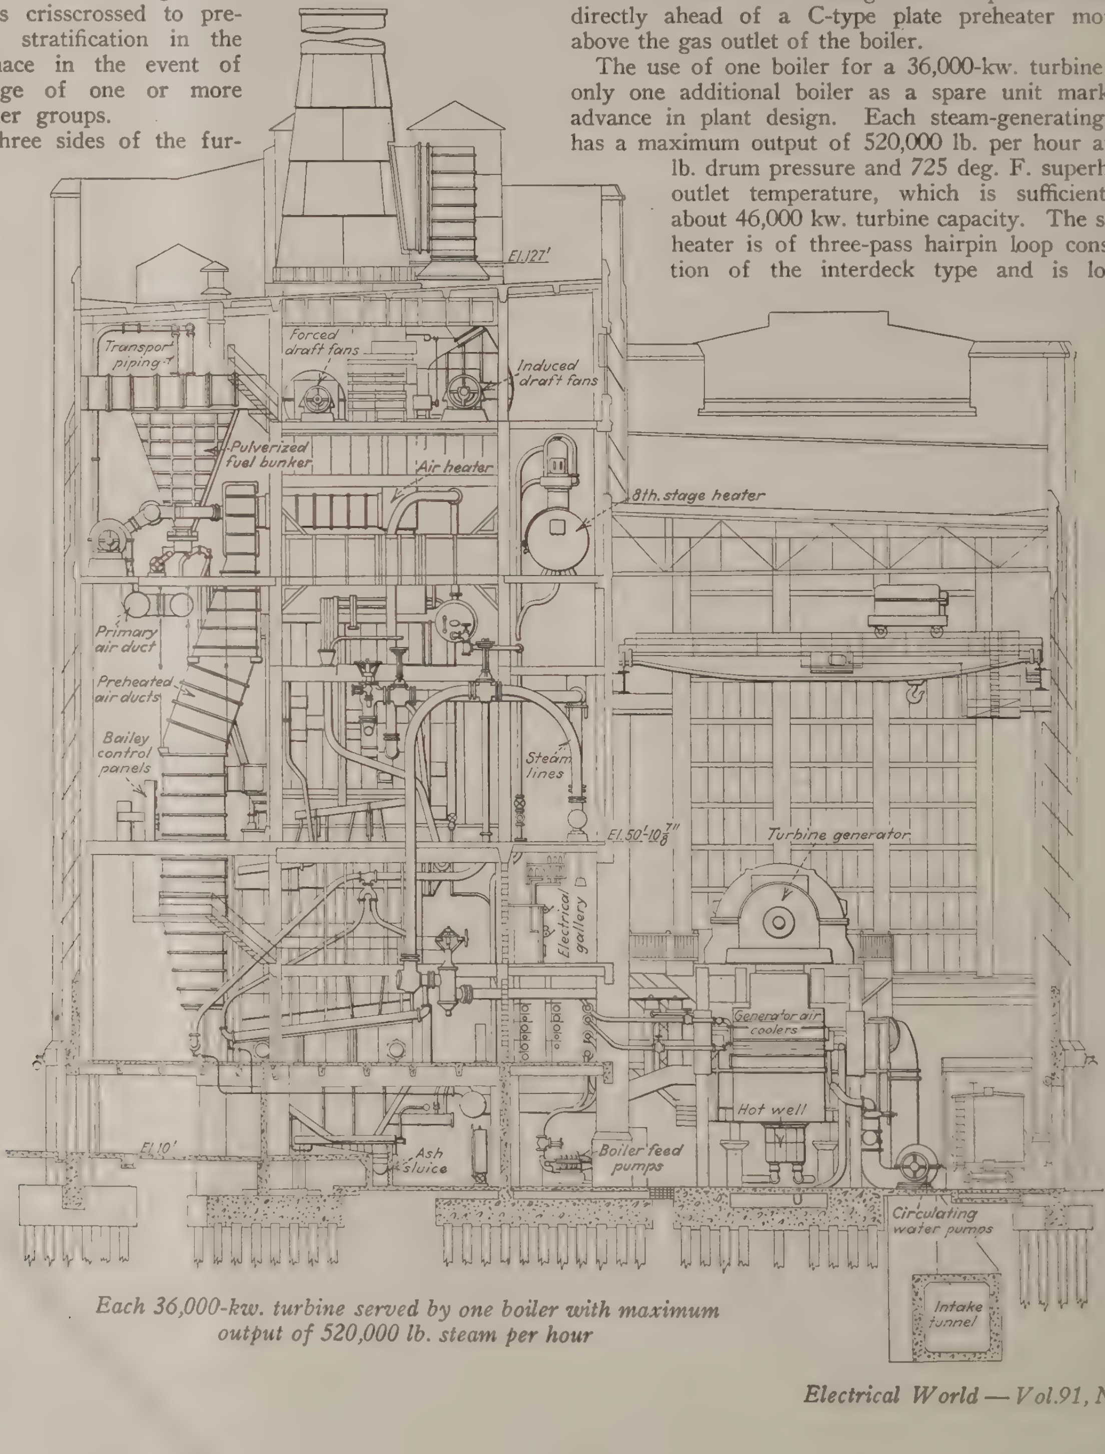
All of the equipment in the preparation plant is electrically driven, using 440-volt, three-phase, 60-cycle, squirrel-cage type motors. There are no circuit-interrupting devices in the preparation plant. Motors are controlled from watertight push buttons operating contactors located in a control room. Sequence interlocks are provided on the controls to prevent flooding or jamming of the coal-feeding system.

---

**Abstract of paper by A. S. Loizeaux, electrical engineer of the Consolidated Gas, Electric Light & Power Company, presented at regional meeting of the A.I.E.E., April 18, 1928.*

Coal is pulverized in the mills so that 70 per cent will pass through a 200-mesh screen. After collection in the cyclones, pulverized coal enters the transport pumps and in combination with compressed air is transported through 6-in. pipe lines about 75 ft. long to the bunkers in the power house. The transport pumps and pipe lines are in duplicate and are so arranged that either pump can handle the output of either or both mills. The two boiler bunkers may be fed by either of the transport lines, selection being obtained by electrically operated transport valves located over the bunkers. The powdered fuel bunkers are insulated to prevent condensation inside the bunker. The coal is fed by four quadruplex screw feeders per boiler to sixteen Lopulco type burners through 6-in. pipes crisscrossed to prevent stratification in the furnace in the event of outage of one or more feeder groups.

Three sides of the furnace are water-cooled by fin-tube surface backed by special tile, rock-wool insulation and steel casing. The front wall is of firebrick, cooled by the preheated secondary air, admitted to the furnace through ports at sixteen levels in this wall. A water screen interconnected with the rear wall circulating system protects the ash hopper.



*Each 36,000-kw. turbine served by one boiler with maximum output of 520,000 lb. steam per hour*

Primary air, used to convey powdered fuel from the screw feeders to the burners, is a mixture of preheated air tapped from the secondary duct and tempered room air. Primary air is supplied by two fans per boiler, connected on the discharge by an air bus, which makes any fan available for either boiler. Two forced-draft fans per boiler furnish the secondary air taken from the room and discharged into a plenum chamber directly ahead of a C-type plate preheater mounted above the gas outlet of the boiler.

The use of one boiler for a 36,000-kw. turbine with only one additional boiler as a spare unit marks an advance in plant design. Each steam-generating unit has a maximum output of 520,000 lb. per hour at 450 lb. drum pressure and 725 deg. F. superheater outlet temperature, which is sufficient for about 46,000 kw. turbine capacity. The superheater is of three-pass hairpin loop construction of the interdeck type and is located between the fifth and sixth rows of boiler tubes, as shown in the illustration at the right.

Hydraulically operated ash gates are provided on the bottom of each end ash hopper which allow the ash to drop on inclined feed plates, from which it is washed into the main sluice by jets of water.

The alternator is a 43,750-kva., 13,200-volt, 62½-cycle machine, which is designed to operate later at 60 cycles. In addition to the main generator there is a shunt-wound shaft exciter, rated at 250 kw., 250 volts direct-current overhung on the main shaft, and beyond this and connected by means of a Fast flexible coupling is an auxiliary generator having a capacity of 1,500 kva.

The turbine is a thirteen-stage Rateau impulse machine of 36,000 kw. capacity and drives the main generator through a Fast flexible coupling. It is a modified form of a turbine of lower normal rating of the non-bleeding type. The initial stages, however, have been opened up to pass the additional steam used in bleeding. Steam is supplied at a normal pressure of 390 lb. and a total temperature of 700 deg. F. Steam is bled at the third, fifth, eighth and tenth stages at full-load pressures of 193, 99, 30 and 9 lb. absolute respectively. The turbine is designed for highest efficiency at 25,000 kw. load, and when bleeding steam at four points the unit can produce a net station send-out of 36,000 kw. A larger output can be produced by bleeding at the two lower points only.

A 30,000-sq.ft., two-pass condenser is bolted directly to the bottom of the turbine exhaust casing and is supported partly by the casing and partly by springs on structural piers on the basement floor. The circulating water passages are so arranged that the cooler water leaving the air devaporizing and cooling section is returned in the second pass in the annular ring of tubes around the outside of the top section with which the exhaust steam first comes in contact. The shell is eccentric with the tube sheet, providing a steam belt which on one end extends to the hot well, and prevents excessive condensate depression. The tubes are rolled into both tube sheets.

### Generator Cooling

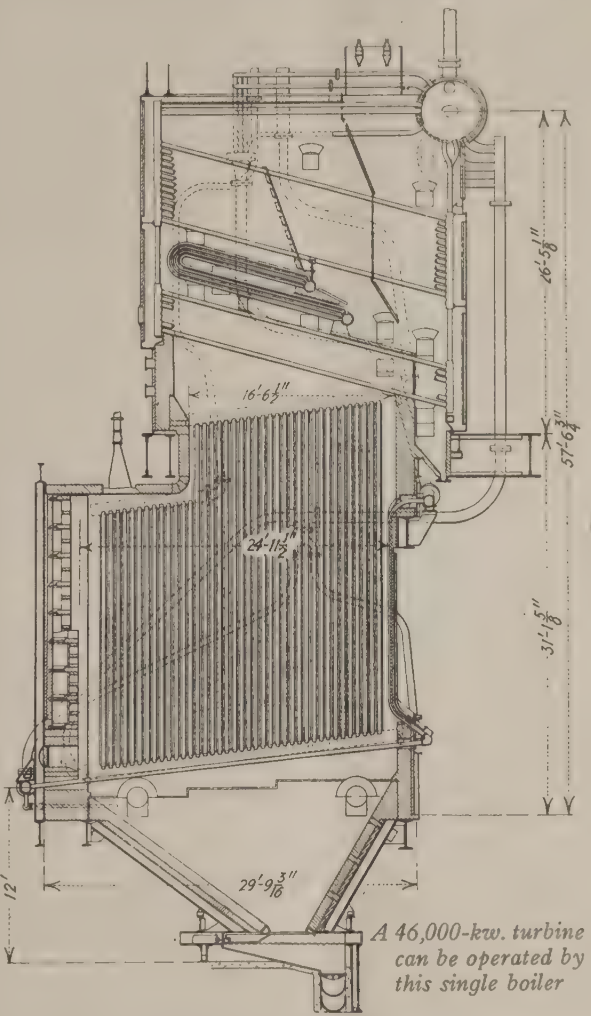
Both the main and auxiliary generators have closed recirculating air cooling systems with two banks of coolers in each, one bank using condensate and one harbor water. The harbor water coolers are connected in parallel with the condenser circulating water system. Condensate cooling is sufficient except for the summer months. The harbor water bank alone will provide sufficient cooling for maximum requirements.

Air is removed from a devaporizing section at the bottom of the condenser by a steam-jet air pump provided with a two-pass intercondenser, cooled by condensate only. Vent steam from the two top stage bleeder heaters and from the vent condenser of the deaërating heater is also condensed in the intercondenser. The exhaust from the second stage jet is condensed in the after condenser.

IMPORTANT RATIOS FOR GOULD STREET STATION

| | Present | | Ultimate | |
|---|---|---|---|---|
| Condenser surface per installed kilowatt, square feet | 0.833 | | 0.833 | |
| Circulating water per installed kilowatt, gallons per minute | 1.25 | | 1.25 | |
| Kilowatt installed capacity per boiler | 18,000 | | 28,800 | |
| Boiler heating surface per installed kilowatt (including water screens) | 1.617 | | 1.009 | |
| Furnace volume per installed kilowatt, cubic feet | 1.167 | | 0.729 | |
| Furnace volume per rated boiler horsepower, cubic feet | 7.22 | | 7.22 | |
| Square feet of area and cubic feet of volume of buildings per installed kilowatt | | | | |
| | Present | | Ultimate | |
| Turbine room | 0.1903 | 16.32 | 0.1523 | 13.06 |
| Boiler house | 0.2333 | 27.20 | 0.1400 | 16.33 |
| Coal preparation plant | 0.0776 | 5.51 | 0.0388 | 2.755 |
| Switch house | 0.0776 | 7.92 | 0.0388 | 3.58 |
| Total buildings | 0.5788 | 56.95 | 0.3699 | 35.725 |

Circulating water from the Patapsco River passes through bar iron trash racks and traveling water screens into an intake tunnel which will extend the length of the turbine room. Each condenser is supplied by two motor-driven pumps of 20,000 gal. per minute capacity each, both of which are required under full-load conditions in the summer. A steam-jet ejector is used for priming the circulating water pumps.

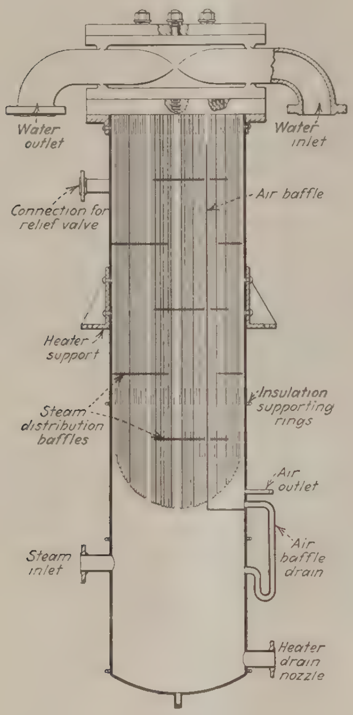


*A 46,000-kw. turbine can be operated by this single boiler*

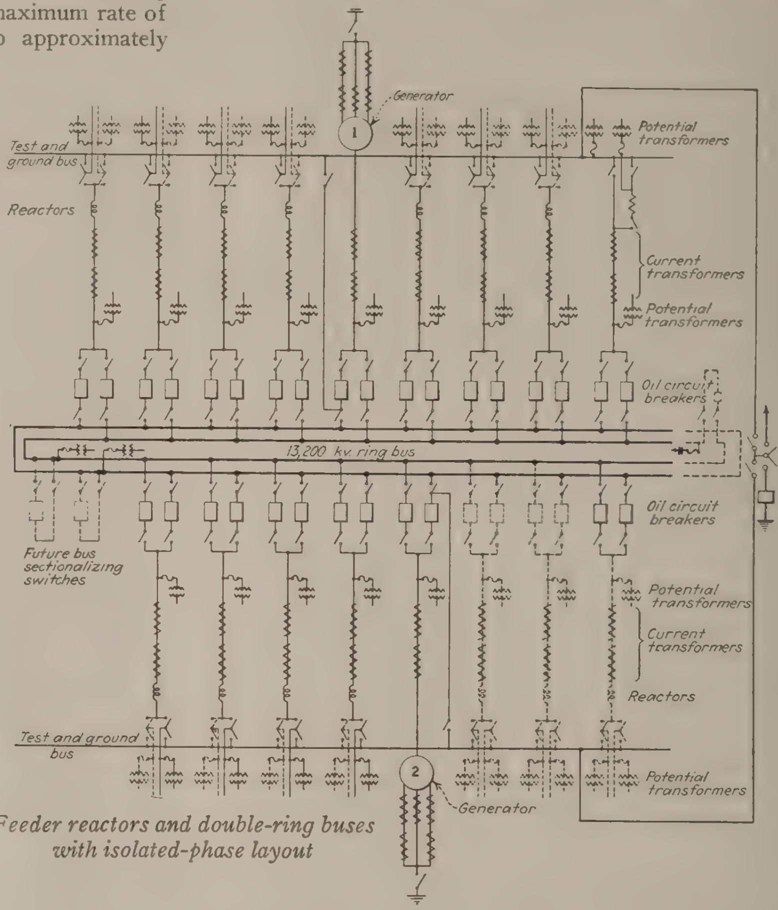
It has sixteen powdered coal burners, fin-tube cooled side walls and furnace measuring about 25 ft. deep by 31 ft. high.

The third-, fifth- and tenth-stage bleeder heaters, the evaporator condenser and the after condenser are of the vertical closed type with four passes each. The construction of these heaters is shown in an accompanying illustration.

The eighth-stage heater is of the direct-contact deaërating type in which part of the bled steam is used in a section into which the condensate is sprayed through jets and part is used in another section similar to the open type feed heater in which trays are located and from which the air is removed. The pressure in the heater varies as the bled steam pressure varies. This heater is in the boiler house at an elevation of 80 ft. above the boiler feed pumps, which take their water from it. With a shell capacity of 6,400 gal. it serves as a closed surge tank. The only condensate in the cycle which comes in contact with air is the condensed drip in the after condenser, which passes through the deaërating heater on its way back to the boiler.



*Hairpin type construction used for bleeder heaters and evaporators*



*Feeder reactors and double-ring buses with isolated-phase layout*

Make-up is supplied by a low heat level interstage evaporator of the vertical single-effect recirculating film type, using city water as feed at a maximum rate of 10,000 lb. per hour, corresponding to approximately 2½ per cent of the total full-load turbine steam flow. Fifth-stage steam is used and the vapor is condensed in the evaporator condenser.

One five-stage motor-driven boiler feed pump of 1,000 gal. per minute capacity is provided for each main unit, with one spare unit of the same size for each group of two units so arranged as to be available for either. A steam-turbine-driven four-stage pump, serving as a boiler protector only, is installed.

### WELDED PIPING USED

The single row of boilers parallel to the row of turbines makes for a very simple steam piping system. Steam is conveyed from single outlets on the Nos. 1 and 2 boilers to a four-neck manifold, from which is taken the No. 1 turbine lead and a tie to a second manifold. The second manifold is a duplicate of the first, with a connection from the No. 3 boiler and the No. 2 turbine in addition to a future manifold. Boiler and turbine leads are 16-in. outside diameter seamless tubing, designed for steam velocities of 9,000 ft. per minute at rated load. Sargol joints, 600-lb. standard, with serrated faces are used throughout, but valve flanges are made up with gaskets and not welded. An emergency closing valve was used on the No. 1 turbine lead, but it will be omitted on the second unit. Motor-operated stop valves are used with additional remote control stations on the turbine platform.

One main and one auxiliary header is used on the boiler feed system with one feed line to each boiler from each header. All feed lines are of seamless steel extra heavy iron pipe size. Eighty-five per cent magnesia insulation with a cement finish covered by 8-oz. army duck is employed throughout.

The generating voltage is 13,700 at the bus and about 13,300 at city substations, the nominal voltage at the point of usage being 13,200. From the power house the energy is carried through the cable tunnel to the isolated phase switch house by means of three 1,000,000-circ.mil lead-sheathed cables per phase. Insulation used on these cables is the standard for substation work, being $\frac{4}{32}$-in. thick, 30 per cent Hevea rubber and $\frac{10}{32}$-in. varnished cambric.

The switch house has a basement and six floors. The side aisles of the basement are used for the high-tension potheads, this being the first and only place the phases come together. The center of the basement has been reserved for a 4,000-volt distribution substation in the future. The first main floor has C phase equipment, the second carries B phase, and the third A phase. The operating mechanisms for the oil switches, bus disconnects and pothead disconnects are located on the fourth floor, together with the connections to the specially calibrated instrument transformers used on the water rate test circuits.

The oil switches on the outer ring bus have a rupturing capacity of 40,000 amp., r.m.s. at 15,000 volts, based on the standard A.I.E.E. duty cycle, and they are built to operate on 15,000 volts, although standard 25,000-volt insulation is provided throughout. All generator and test bus tie circuits are equipped with 2,000-amp. apparatus, while the outgoing feeders have 600-amp. oil switches and disconnects.

*PE*—150-hp. air compressor.
*PF*—75-hp. drier exhauster.
*DW*—10-hp. dock winches.
*BH*—60-hp. barge haul.

The inner ring bus is equipped with switches having a rupturing capacity of 40,000 amp. on the generator and test bus tie circuits only. The feeder switches have a rated rupturing capacity of 30,000 amp.

Each three-phase feeder is equipped with three single-phase reactor coils, one on each phase floor, these coils having an impedance of $\frac{3}{4}$ ohm, which limits a dead short circuit or ground to a maximum of 10,000 amp., which is only one-third or in some cases one-fourth of the rated rupturing capacity of the switch.

Each machine has its own exciter bus which supplies excitation to the fields of both the main and auxiliary generators. Power is usually fed into this bus from the shaft exciter, but an emergency supply is available from a 200-kw. motor-generator set.

Station auxiliaries are designed for 460 volts rather than 2,300, because the lower voltage motors were lower in cost and kept in manufacturers' stocks. It was felt that the lower voltage was also somewhat safer and could be handled well by carbon circuit breakers. Carbon circuit breakers occupy less space than oil switches that would be required for 2,300 volts. Their cost was lower and they are subject to inspection during operation as they are mounted on the front of the auxiliary switchboard. The fire hazard with oil switches is also avoided.

The supply of fuel and air to the boilers and the removal of gas is controlled by Bailey automatic equipment which governs the speed of the forced-draft fans, induced-draft fans and coal feeders. The circuits controlling the fans, feeders, etc., have been interlocked to shut down the equipment automatically in the event of failure of any part of the apparatus which might result in explosive mixtures in the furnace.

The induced- and forced-draft fan controls are the most unique in the plant. Due to the large size of the boilers and the high guaranteed rating of 550 per cent nominal rating, each of the boilers requires 1,500 hp., divided up as follows: Two 200-hp. forced-draft fans, which introduce fresh air to the combustion chamber, and two 550-hp. induced-draft fans which blow the hot gases up the stack.

The control for each fan consists of a low-speed secondary regulating resistance drum, a transfer switch for changing the number of poles by altering primary connections, a high-speed secondary regulating resistance drum, a balanced high-speed drum for the last five-speed points, a torque switch for starting and the necessary circuit breakers and relays for interlocking and automatic protection. This combination of apparatus provides approximately 55 speed points for each fan.

In order to start up the fans it is only necessary to push a button. When the automatic combustion control calls for more draft the drums begin to rotate, the primary circuit breakers are automatically closed, the torque switches revolve until the motor starts up and the drums are set on the desired operating point automatically. In the case of the induced-draft fans, stack dampers are controlled by the same combustion control drive and a range of natural draft is utilized before the primary breakers close and the fans start. The speed range of the induced-draft fans is from 110 to 870 r.p.m. and on the forced-draft fans the speed range is from 145 to 1,170 r.p.m.

Primary air fans are controlled by manually operated secondary regulating resistance drums having eleven points, five of which are balanced. Their speed range is from 700 to 1,750 r.p.m.

An elaborate system of interlocks has been provided to take care of emergencies in operating and to prevent situations which might cause an explosion of the powdered coal mixture in the boilers. Relay protection is provided to trip the fan circuit breakers on loss of 460 volts service. In case the two induced-draft fans are tripped the two forced-draft fans are automatically removed from the line to prevent the formation of positive pressure in the furnaces. If, at this time, the combustion control is still calling for mechanical draft, three of the four coal feeder motors are shut down.

The coal feeder motors are 5 hp., 250 volts, d.c., inclosed, and have a speed range of from 400 to 1,600 r.p.m. The 500-hp. boiler feed pumps are controlled by motor-operated drums having 36 points and a speed range of from 1,400 to 1,750 r.p.m.

The 125-hp. condensate pumps have 24-point hand-operated secondary regulating resistance drums with eight balanced points, giving a speed range of from 1,400 to 1,750 r.p.m. The 175-hp. circulators also have hand-operated drums with a speed range of from 175 to 350 r.p.m. in eleven steps, five of which are balanced.

Throughout the design of the Gold Street plant the object was to secure maximum reliability with minimum total costs per kilowatt-hour. By total costs is meant not only operating labor and superintendence, maintenance and fuel cost, but fixed charges on the investment. This criterion was used in the choice of apparatus, the cost of the apparatus being weighed against its ability to reduce production costs.

The actual cost of the first unit and the estimated costs of three additional units are shown in the following table (the estimated cost of the completed plant of 144,000 kw. being $88.26 per kilowatt):

| | One Unit (Actual) | Two Units (Estimated) | Three Units (Estimated) | Four Units (Estimated) |
|---|---|---|---|---|
| 1. Investment cost as per report of June 20, 1927... | $4,681,821 | $7,396,224 | $10,090,322 | $12,709,909 |
| 2. Capacity, kilowatts...... | 36,000 | 72,000 | 108,000 | 144,000 |
| 3. Cost per kilowatt......... | $130.05 | $102.73 | $93.43 | $88.26 |

The wide spread between the cost per kilowatt of the first unit and the cost per kilowatt of the completed plant is due to the many items included under the first unit, which are designed for the completed plant, such as land, receiving platform for coal storage, coal handling, preparation plant, etc.

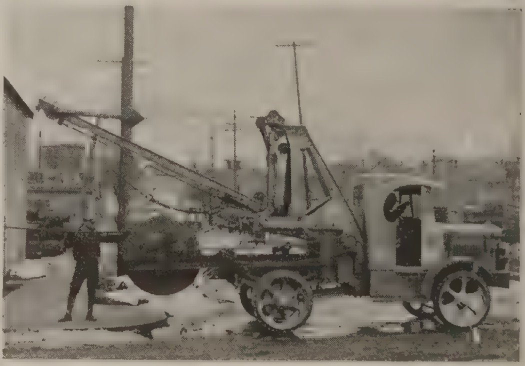
The capacities given in the above table are the net send-out capacity with four-stage bleeding.

Under two-stage bleeding conditions capacity is increased considerably and a net send-out capacity of 40,000 kw. is readily obtained, and will be obtained in the event of need, for peak-load conditions. Figuring this higher capacity the investment costs become as follows:

| | One Unit (Actual) | Two Units (Estimated) | Three Units (Estimated) | Four Units (Estimated) |
|---|---|---|---|---|
| 1. Investment cost as per report of June 20, 1927... | $4,681,821 | $7,396,224 | $10,090,322 | $12,709,909 |
| 2. Capacity, kilowatts...... | 40,000 | 80,000 | 120,000 | 160,000 |
| 3. Cost per kilowatt........ | $117.05 | $92.45 | $84.08 | $79.44 |

The investment figures given include all expenses of every nature in connection with this plant, covering such items as preliminary engineering, old buildings used, interest during construction and during tuning up period, also a portion of the floating equipment of the company properly allocated to serve this plant.

## Cable Pulled by Reel on Derrick Truck



THIS power-driven wire reel has been found to reduce time and labor greatly in removing large overhead cables and indicates one of the many uses for a 10-ton derrick truck utilized by the Northwestern Electric Company, Portland, Ore. The cable-pulling attachment can be removed easily and the derrick used for handling heavy material and equipment.

# Proper Location of Disconnecting Switches Insures Safety

By W. Specht
*Switchboard Engineering Department, General Electric Company*

DISCONNECTING switch placements should be carefully planned if adequate safety is to be afforded operating men. Not only is the question of proper height involved but the width of aisles is also important. These values have been analyzed, and as a result the accompanying chart has been developed.

The curves inclose areas from which the safe location of disconnecting switches using 4-, 8-, 12- or 16-ft. switch hooks can be determined. These areas are based on a minimum operating angle of 30 deg. from the vertical and a proper maximum and minimum height for the lower end of the operating hook, permitting the operator to use both hands even in the maximum position, thereby assuring easy and steady manipulation of the hook.

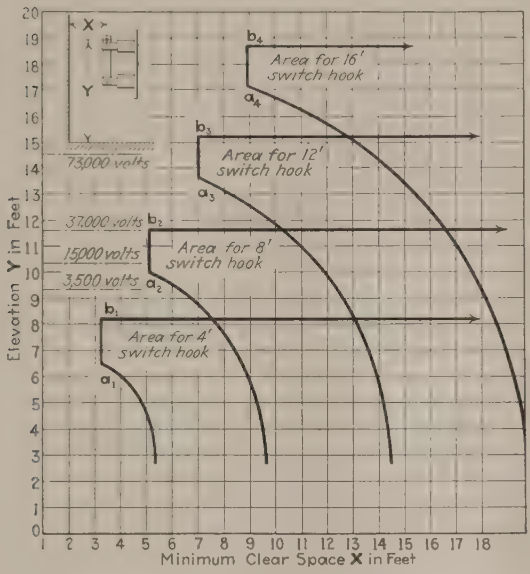


*Chart aids in designing switch placements*

If the width of the aisle is given and therefore the dimension $X$ is known (see upper left-hand corner of illustration) it is then an easy matter to determine the possible dimension $Y$ by finding the value of $X$ on the horizontal scale and following it vertically until the circular curve bounding the area corresponding to the switch hook used is reached. Between this point and the point where the line leaves the area, vertically above it, lies the possible dimension $Y$. Likewise, if $Y$ is given, the minimum dimension $X$ can be determined in a similar manner.

Assume that a 15,000-volt disconnecting switch is to be mounted in an aisle 6 ft. 7 in. wide, which will require the use of an 8-ft. operating hook. The distance from the wall, on which the disconnecting switch is mounted, to the eye of the blade is given as 11 in. What is the permissible $Y$ dimension?

Taking the above dimensions into consideration, $X$ is equal to 79 in. minus 11 in., or 68 in. (5 ft. 8 in.). Following the vertical at $X = 5$ ft. 8 in. it will be seen that the circular curve is intersected at $Y = 9$ ft. 8 in. and the horizontal line of this area (directly above) at $Y = 11$ ft. 8 in. This means that the disconnecting switches may be mounted with the $Y$ dimensions between 9 ft. 8 in. and 11 ft. 8 in. and at both extremes can be conveniently operated by an 8-ft. switch hook. Values of $X$ falling to the left of the vertical line indicate too narrow aisles.

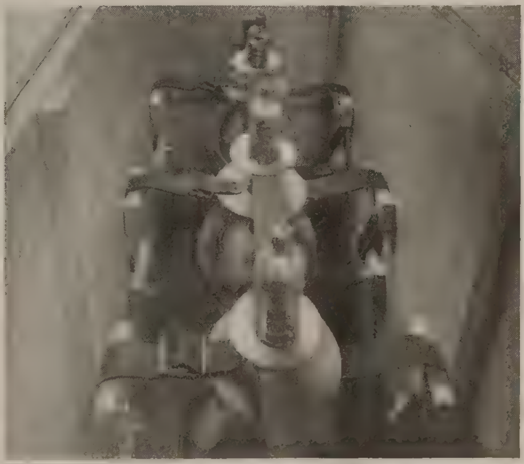
Assume now that the height $Y$ is limited, say, to 9 ft. 6 in. Then find the horizontal line corresponding to this dimension and follow it until it cuts the vertical or circular curve bounding the corresponding area (in this case for the 8-ft. switch hook). In the present case it will be found that the circular curve is intersected at $X = 6$ ft. 0 in., which is the minimum dimension. Of course, there is no limit for $X$ maximum and therefore the areas in the illustration have no boundary on the right-hand side.

The marking along the vertical scale 3,500 volts, 15,000 volts, etc., are the minimum vertical dimensions $Y$ for the voltages indicated when disconnecting switches need not be protected by barriers. This makes it easy to see whether barriers must be furnished after the $Y$ dimension has been determined. For instance, in the last example with the $Y$ dimension = 9 ft. 6 in. and a 15,000-volt disconnecting switch it is immediately seen that barriers are required.

---

# Carrier for Kenotron Tubes

By R. W. Chadbourn
*Department of Standardizing and Testing*
*Boston Edison Company*

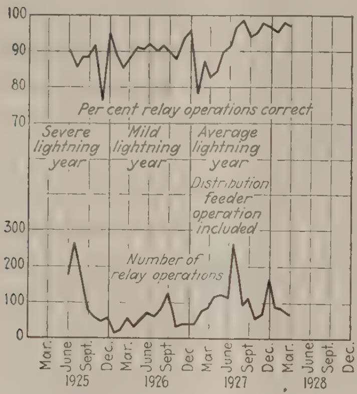


TO SAFEGUARD kenotron tubes against breakage during transportation in a portable testing unit recently built for the Edison Electric Illuminating Company of Boston a special box was constructed to carry five tubes in a vertical position, as shown in the accompanying illustration. Each tube is held in place by two short straps of canvas secured to the sides of the box. In the center of each strap is a round piece of leather with a hole cut to fit the end of the tube. The top strap has a safety buckle which permits its removal from the tube. The tube can then be lifted out of the hole in the lower strap. As a further safeguard a long strap runs longitudinally through the box and acts as an anchor for all five tubes.

# Direct Benefit of Field Testing of Relays

By B. M. Jones
*Equipment and Protection Engineer*
*Duquesne Light Company*

THE direct benefit of field testing of protective relays is the improvement in the service rendered and the improvement in the operating performance of these relays with their associated devices, the first being by far the most important and the object for which all operating companies strive.



*Relay performance improved since adopting field testing*

The accompanying graphic record shows the relay operating performance of the Duquesne Light Company from June, 1925, to and including the first quarter of 1928, and the benefit of the field relay testing improved correspondingly with the relay performance. The average for the portion of the year 1925 was 88.4 per cent, for the year 1926 91 per cent, for the year 1927 92.5 per cent, and for the first quarter of 1928 96.7 per cent. This percentage of correct performance includes the performance of the relays themselves, the current transformers, the potential transformers, the tripping battery, all control and switchboard wiring, the mechanical adjustment of the breaker and its auxiliary switches and all devices that go to make up the automatic circuit-interrupting device. This method of rating the relay performance is in accordance with the recommendations of the relay sub-committee of the A.I.E.E.

With a simple transmission system the adequate relaying of the lines and equipment is relatively simple and field testing is not so important. However, with a complicated transmission system and the various complicated relay schemes that must be used, the matter of field testing becomes of utmost importance, and to the relay engineers and operating departments of our company this method is the most dependable means that we know of to assure the relays and associated devices being in the proper condition for isolating faulty equipment in the minimum time.

A large part of the improvement shown on the graph is derived from the testing of directional line ground relays by actually grounding the line. The article in the ELECTRICAL WORLD of March 17 entitled "Field Testing of Relays," by Messrs. Evans and Salsbury of our company, describes in detail the methods used for the field testing of relays. The test plan involves the use of a truck-trailer with voltage regulators, circuit breaker, storage battery, water barrel load, instruments and auxiliary and control equipment.

It has cost some money to make the field relay tests, but our company feels that this investment has returned very large dividends, and such tests are not being restricted in any manner.

# Mercury-Arc Rectifier Inspections

By O. M. Ward
*Assistant Electrical Engineer Milwaukee Electric Railway & Light Company, Milwaukee, Wis.*

INSPECTION of mercury-arc rectifiers on the Milwaukee Electric Railway & Light Company system must be made once a week, and if anything unusual is noticed during inspection or operation a verbal report must be made to the chief operator as soon as it is possible to do so.

The report form which follows is made out in duplicate, one copy being sent to the chief operator and the other kept at the station, so that the inspector may have the guidance of previous inspection:

## *Inspection Report for Mercury-Arc Rectifier Stations*

Date................

**26,400-Volt Equipment:**
Insulators. Are any broken?......Do any show leakage?......
Lightning Arresters. Condition..............................
Disconnecting Switches. Is there any signs of heating?........
Do switches show mechanical defect?....................
Fuses. For auxiliary transformers.
(Inspect every three months) ............................

# Operating Experiences

## at Gould Street Station*

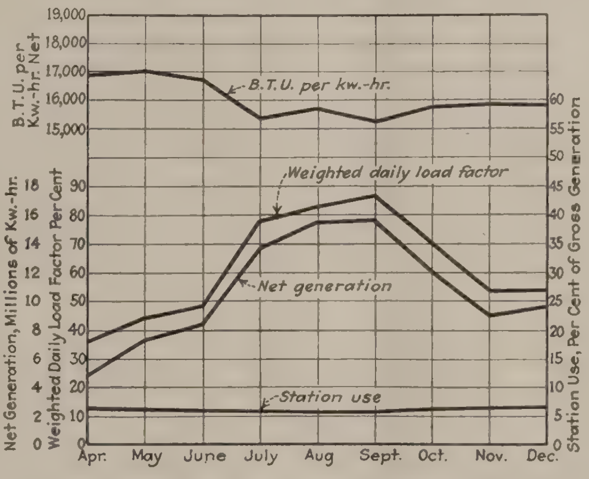
Performance obtained during initial operation of the new station of the Consolidated Gas, Electric Light & Power Company of Baltimore and methods adopted to overcome usual preliminary troubles

TROUBLES which have developed in the coal-handling equipment of the new Gould Street station of the Consolidated Gas, Electric Light & Power Company have not resulted in any great amount of inconvenience. Of major importance was the failure of some parts used in propelling the airplane tripper and its unloader belt, the drive being from the main conveyor belt by means of gearing and clutches. One of these failures resulted in a runaway condition, with considerable damage narrowly averted. The weakness was obviated by adopting a cable-haulage arrangement actuated by a separately controlled motor.

A pulverized-coal system handling wet coal is subject to many ills, and it is difficult to obtain proper flow at many of the points where gravity is the moving force. Very unsatisfactory grinding is obtained with wet coal. After the coal is ground, some of it forms a pasty mass and sticks at almost every conceivable point. A mucky mass very often collects in the mill, choking up the air passages. Vent lines become choked. Cyclone separator discharge lines become plugged. Transport pumps and lines become plugged. The coal cakes in the pulverized coalbins and arches over the feeder screws at the boiler, causing burners to become extinguished. Even the burner pipes become so choked that in many cases it is necessary to take pipes down for cleaning, as rapping on the pipe is often ineffective. There is also much difficulty from irregular feeding of the coal to the furnaces, which greatly reduces the furnace efficiency.

The steam-heated grid type driers originally installed were found to be inadequate for our conditions. As already explained, the delivery of fine coal to the drier resulted in arching and inability to get the coal to flow through the drier. There was also additional trouble due to the pulling along of considerable coal by the air used to remove the moisture. A large amount of air is necessary, and while it was put through a cyclone separator, the separation was incomplete, causing a considerable loss of coal. The coal recovered in this cyclone separator was discharged into the hoppers of the transport pumps. There was the additional objection that much of this coal was coarser than desired. Some of the drier grids were removed to better these conditions. While feeding was bettered, drying was less complete.

Furthermore, the amount of moisture removed was not so great as was necessary for the satisfactory milling and handling of the coal. Failure in this respect caused the consideration of other means of obtaining the desired result. We believed that the most reasonable scheme would be that of drying the coal, which is in a finely divided state, in the air circulatory system of the pulverizing mills, and that it should give up its free moisture very readily. Due to the relative locations of the mill house and boiler room, it was not feasible to use either stack gases for supplying the heat required or the air vented from the mill system for primary air. Accordingly, it was decided to heat the make-up air by means of high-pressure steam, so as to obtain the maximum temperature, thereby permitting us to supply the necessary heat with a minimum of air. This permits of using apparatus that is much more compact and reduces to a minimum the amount of fine coal that is lost in the vented air. The mill drier is not effective in drying the coal until it enters the mill, and this, of course, does not help the flow of coal to the mill. High moisture, however, has caused no appreciable difficulty in feeding the mills, since the grid driers have been removed. The mill drying system is performing very satisfactorily and has practically eliminated the many annoyances incident to wet coal. In regular operating practice the mill drier has been successful in reducing the moisture content of the coal from 6 per cent entering the mill down to 1.7 per cent leaving the mill.



*Nine months' records at new Baltimore station*

Attention was concentrated on securing dependable operation and not on output.

The air washer as originally installed for use with the grid type driers did not remove the coal dust to a sufficient degree. It was also inadequate when the mill

---

*Abstract of paper by A. L. Penniman, Jr., and F. W. Quarles of the Consolidated Gas, Electric Light & Power Company, presented at the regional meeting of the A.I.E.E., Baltimore, April 18, 1928.*

type drier was put in commission. In order to obtain satisfactory removal, it was necessary to increase both the amount of steam and water used. At the present time approximately 1,150 lb. of steam and 2,000 gal. of water are used per hour, with a dust concentration of about 0.8 grain per cubic foot of air entering the washer, the amount of air handled being approximately 1,240 cu.ft. per minute.

### Mills Work Well

On the whole, the pulverizing mills have performed very satisfactorily, although, of course, there is considerable wear of the grinding rollers and bull ring of the pulverizing mills and of the blades and wearing plates of the mill exhausters. These mills, designated by the manufacturer as of 20 tons per hour capacity, have pulverized at an average rate slightly in excess of 24 tons per hour each, the coal leaving the mill having an analysis about as follows:

| | |
|---|---|
| Moisture | 0.76 per cent |
| Volatile | 25.28 per cent |
| Fixed carbon | 63.76 per cent |
| Ash | 10.20 per cent |
| Sulphur | 2.02 per cent |
| Amount through 200-mesh sieve | 74.2 per cent |
| Amount through 100-mesh sieve | 89.4 per cent |
| Retained on 40-mesh sieve | 0.4 per cent |

At times there has been some difficulty experienced due to coal hanging up in the cyclone separators or in faulty delivery to the hoppers of the transport pumps, because of improper functioning of the flappers of check valves or the choking of vent lines from hoppers to suction pipes of mill exhausters. One other difficulty is the collecting of a mucky mass of coal and water in the chamber of the mill that receives the air returned from the cyclone separator. A muck-collecting pocket installed on one of the mills served to alleviate this condition somewhat. However, the better drying obtained when the mill type drier was installed eliminated all trouble of this nature.

### Coal Transport System

There was considerable trouble with the operation of the pulverized-coal transport system when the plant became active. Most of the difficulties resulted in the plugging of transport lines, which, being new and rough, were accredited with the responsibility for part of the troubles. The starting up of this system occurred during cold weather, and this, in conjunction with the faulty performance of the driers, was responsible, no doubt, for the greater portion of the plugging. Also, the size of the hoppers above the transport pumps was thought to be too small for even delivery to the screws of the pumps and partially responsible for the pumps plugging. Accordingly, they were increased in size by adding height with filler pieces having rectangular openings to conform to the hoppers. It was discovered that considerable water collected in the cylinders of the pumps after being shut down several hours. Keeping the pumps drained was the logical answer to this difficulty. Increasing the air pressure on the nozzles of the pumps also helped to keep the boilers supplied with coal. Later, when the transport lines were worn smooth and the mill drier system was in service, trouble with the transport system practically disappeared.

Coupled with the difficulties of pumping the coal was the difficulty of the sticking of the transport line switching valves. This was alleviated somewhat by applying brass liners to the valves. This has not been an absolute remedy, as it is necessary to operate the valves frequently, and even then occasionally to dismantle them for complete cleaning. A careful analysis of the factors involved is now under way and it is hoped that this will result in eliminating any abnormal routine operation of the valves to prevent their sticking.

The amount of power used in the grinding and transporting of the pulverized coal averages approximately 19.6 kw.-hr. per ton of 2,000 lb. The expenditure for the maintenance of pulverizing equipment has been approximately 13.9 cents per ton.

### Boiler Room Operation

The greater amount of effort for tuning up and making structural changes to approach or exceed design conditions has been put forth in the boiler room. While efforts have been made to hasten the process, at this date there are several matters that have not been brought to a satisfactory state.

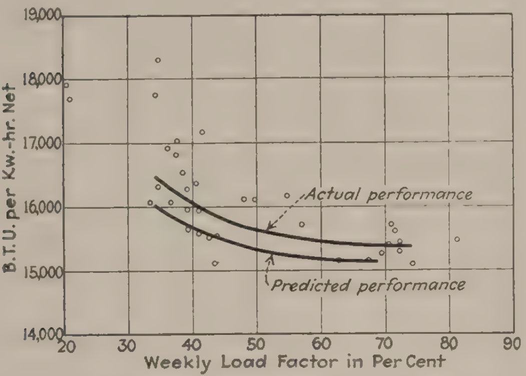
At the outset considerable difficulty was experienced with poor feeding of the coal due to insufficient drying and condensation on the walls of the bunkers. It frequently became necessary to empty a bunker of the coal which would flow and then have men enter the bunker and scrape down the pasty masses of coal clinging to the walls and arched over the feeder screws. This condition was eliminated almost entirely by the mill type drier when it was put in operation. Since our early experiences, No. 1 bunker has been covered with heat-insulating material and an investigation has been made on No. 2 bunker by forcing preheated air over the coal from one end to the vent at the opposite end to reduce the humidity of the air over the coal. The use of hot air results in less condensation on the walls, but there also is an increase in the amount of coal lost out of the bunker vent. A combination of heat insulation with the use of hot air would probably give a still better feeding performance.

With the coal-feeding equipment originally installed it was impossible to reach the maximum designed capacity, part of the fault being insufficient motor speed. However, sufficient coal could not be supplied after the motor speed was increased to that designated. New screws, having a considerably greater capacity, were furnished for one boiler. These screws caused flooding to take place at lower ratings, resulting in very dense smoke and, in one or two cases, in the loss of much coal to the ash hoppers. Also, these screws had so much capacity that it was considered advisable to abandon them and hob out the original screws. Flooding also took place on these modified screws, and to eliminate this spring-loaded disks were applied to the discharge end of the screws to provide a uniform resistance to the coal being fed. These very successfully reduced the pulsations experienced with the feeders having greater capacity than the original.

The controls of dampers in the various ducts were originally unsatisfactory, in that it was possible for sudden changes to occur if the hand slipped on the operating chains. In the case of the primary air system, a damper got out of control and was responsible for an explosion occurring in the furnace of No. 1 boiler, this explosion resulting in bulging of the steel casing and the bending of several side-wall tubes. By applying worm wheels and sectors to these dampers the control has been made positive and easier to manipulate.

In order to guard against future explosions displacing the furnace sides, a horizontal steel buckstay was applied around the middle of the furnace for additional strength, as it was assumed that the air and gas passages should furnish sufficient relief for the expansion of the products of combustion resulting from such explosions. The boiler control, also, was provided with some features to eliminate some of the provoking causes of explosions. Furnace contactors were provided to trip out three of the four coal feeder motors per boiler on the occurrence of excessive furnace pressure. Primary air pressure contactors were arranged to trip out the same three feeder motors and to turn on the steam to the burner aspirators on the occurrence of low primary air pressure. The forced-draft fan control is arranged to trip if both induced-draft fans are tripped. Since these modifications have been made no occasion has arisen necessitating their functioning.

Changes have been made in the burner design with respect to what is termed the tertiary air; that is, the heated air which is forced downward around the burner nozzle. These changes have been made with the idea of producing a longer downward sweep of the flame with less and hotter primary air. The present indications are that the new arrangement is very beneficial.



*Predicted and actual performance at Gould Street*

The points plotted for actual performance show quite a wide variation, not only because of the changes made in the plant during the year, but also because comparatively small error in estimating coal causes a large error in consumption when consumption is least. It is expected that the installation of automatic coal scales to weigh the coal entering the mills will greatly decrease this error.

Experimental observations were resorted to in order to obtain a better distribution of air across the furnace. The number of port openings in the front wall was substantially reduced, which, by proper selection of the ones to be closed off, improved the distribution, produced greater turbulence and also made available a higher tertiary air pressure. It was then possible to exercise more control over the tertiary air.

The spring-loaded dampers governing the flow of secondary air to lanes in the front wall have performed unsatisfactorily at times and it has been necessary to provide hand control to those governing the air admitted by the four uppermost lanes. It is now considered desirable to have all of the spring-loaded dampers operated by hand from the main boiler floor.

Some difficulties have been encountered with slagging of the lower rows of boiler tubes. This slagging usually occurred after the boiler had been carrying about 400 per cent rating continuously for 48 hours or longer. Little trouble was experienced when less load was carried at night than in the daytime, and it has been noticed that much slag which had accumulated when operating at high rating fell off when the rating was reduced for several hours. On one of these occasions when a high rating had been maintained for longer than 48 hours an attempt was made to cause the slag to drop by increasing the excess air, but this apparently had little effect. One proposal advanced to prevent this trouble was to remove every other tube in the bottom row of boiler tubes, which would mean that the spacing of this bottom row would then be approximately the same as that of the water screen and, consequently, slagging would be greatly reduced. The boiler manufacturer has recommended against removal of these tubes and, instead, suggests removing every other tube in the lower row and installing deformed tubes which would have a drop of 7 in., thereby accomplishing the same result with no loss in heating surface.

The air heaters are arranged with straight vertical flue gas passages and U-shaped air passages, the air entering and leaving on the same side of the heater, thereby providing very unequal resistances to flow in the air lanes. The result of this was a wide spread in the air temperatures leaving the air heater, there being about 200 deg. F. temperature difference between the top and bottom of the duct discharging air from the heater. A deflecting-type baffle was applied to guide the air toward the lanes having the longer paths. Another scheme which was also experimented with consisted of adding resistance at the air inlet to the shorter paths, the increased resistance to flow of air being obtained by the application of metal strips. The two schemes materially helped the situation and were of about equal merit, although neither attained the desired result. Both schemes are objectionable from the standpoint of power loss caused by the increased duty placed on the forced-draft fans. The air heater manufacturer is now taking the necessary steps to improve the performance of this apparatus.

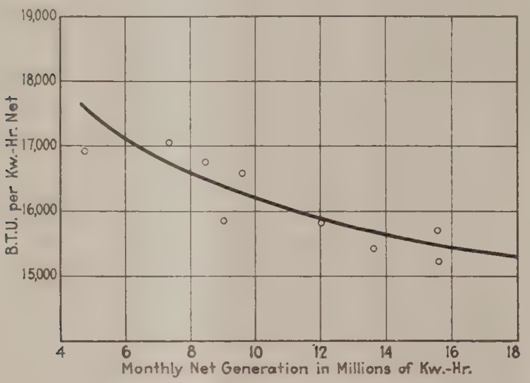
The bearings on the primary air and induced-draft fans are of the ring-oiled type, provided with an integral oil cooler built into their bases to eliminate the necessity of separate oil pumps for the circulation of the oil and also to permit the use of harbor water for cooling. There was some trouble from the leakage of water into the oil reservoirs, which was eliminated by a slight change in the design of the coolers.

The induced-draft fans are of the plate type because of the high duty imposed by the requirement of handling 135,000 cu.ft. per minute of 450-deg. F. gases against a static head of 15.8 in. of water. These fans have given excellent service except for some slight vibration due to the bearing pedestals being somewhat light. This has been corrected by the application of bracing. Two failures of an induced-draft fan motor have occurred, the reason for which cannot be ascribed to overload or faulty control.

Five failures of fin tubes constituting the back furnace wall have occurred. These tubes have all failed in the same manner and almost at the same spot, namely, the outside of the top bend of the rear wall tubes near the sides of the furnaces. In one case a large bulge was noticed before an actual rupture occurred. The water circulation is to be investigated to determine whether or not there is considerable difference in rapidity of water circulation in different parts of the back wall. The obtaining of this information will no doubt make possible a satisfactory analysis of this condition.

Because of the high rating for which these boilers are designed, it was necessary to supply two 6-in. feed-water regulating valves. It was found that the thermostatic tubes of the feed-water regulators were not sufficiently powerful to operate the valves properly. New pistons were designed by the manufacturer in an effort to reduce the friction, which was apparently caused by water flow, since the friction was quite low when no water was flowing through the valves. The new pistons did not prove entirely satisfactory and attention was directed toward the use of hydraulic power, utilizing the thermostatic tube to actuate only a pilot valve. Operation was so much more satisfactory that the manufacturer equipped all the regulators similarly.

Soon after starting the plant it was determined that the moisture content of the steam leaving the boiler drums was higher than desirable. The boiler manufacturer has developed and installed a new type of baffle which has produced excellent results. This improvement should be of much benefit in the maintaining of cleaner surface on the interior of the superheater tubes, since the moisture, of course, carries solids in solution. It also will reduce the duty on the superheater for a given temperature of steam leaving the superheater.



*B.t.u. per net kw.-hr. at different monthly outputs*

The plant operated for a large portion of the year 1927 with lower superheat than the design value. It was held advisable to delay the raising of the steam temperature until other apparatus which would influence the result had been tuned up. Just recently the baffling of the gas passage at the superheater has been changed to give the desired steam temperature. The remaining feature to be reckoned with is the pressure drop of the steam through the superheater, this being approximately 35 per cent higher than expected.

As to the matter of combustion control, several difficulties were experienced in the burning out or breaking down of coils and grounding of wiring. Discharge resistances were provided to lessen the inductive kick from the coils and wire with varnished cambric insulation was used in the control boxes to withstand the oily atmosphere. The pole-changing feature of the motors contributed some complications on account of the necessity of providing control overlap.

The combustion control is normally set to maintain a 15 per cent $CO_2$ average across the section of the boiler gas outlet. This setting is interfered with to some extent by a variation in feed water temperature. This is particularly so if the two higher pressure feed-water heaters are cut out of the circuit at 20,000- to 35,000-kw. load on one boiler. An attachment has been designed quickly to correct the meter for this condition and is being installed. The combustion control which we have installed is not suitable for quick changes in load, this having been demonstrated several times. It is our usual practice to operate on semi-automatic control for the quick changes in load which can be anticipated, such as the noontime drop and the morning pick-up.

There are eight 4½-in. high-lift safety valves on the drum and two on the superheater outlet of each boiler, each drum valve having a relieving capacity of 52,500 lb. per hour and each superheater valve 35,000 lb. per hour. While these valves have not been tested for relieving capacity, two occasions have arisen when the entire plant load has been lost in which the safety valves relieved a total of 380,000 lb. per hour satisfactorily. One of these occasions was when an air drill penetrated the high-voltage leads from the main generator, causing the differential relays to trip out the oil switch and field breaker, the other when the throttle valve of the main unit became unlatched. The leakage and maintenance of these valves has been very slight and, as a matter of fact, has not been any higher than has been experienced at the Westport plant on 200-lb. pressure service.

There are three ash gates per boiler, 41 in. x 56 in., actuated by oil-operated cylinders which at times have refused to move due to friction, distortion and failure of cast-iron plates. In certain places where two ferrous materials rub on each other, one of them has been replaced by non-ferrous material, clearances have been increased and the cast-iron support plates have been reinforced with steel. The result has been almost complete elimination of the sticking difficulties.

### TURBINE ROOM

Since No. 1 turbine was placed in operation slight trouble has been experienced with it. On one occasion sticking of the primary control valve stem occurred. This stem was made of "Ascoloy" and slides in a Monel bushing. These two metals apparently are not very satisfactory for sliding contact. The Ascoloy stem was replaced with one of medium-carbon machinery steel and the bushing enlarged to give a greater amount of clearance, the packing being relied upon to serve partially as a guide. It is contemplated that an Ascoloy stem will again be used, but with a cast-iron bushing so contained in a steel cage that the cast iron will not be able to break up and go through the turbine. Another difficulty which was experienced soon after the turbine was started up the first time was undesirable vibration of the throttle and control valves. This was remedied by the elimination of undue play at certain points and the redistribution of the weight of the pipe, control and throttle valves among several hangers.

The main condenser, while of somewhat radical design, in that the tubes are rolled into the tube sheet at both ends, has given but little trouble. The noticeable leaks which have occurred have been very few. In spite of the fact that the circulating water is high in salt content, we have been able to maintain the solids in solution in the condensate at a very low value. Computations made before the plant was put in commission indicated that if the leakage was as high as usually obtained with packed tube condensers it would be necessary to blow down the boilers very frequently, or continuously, in order to maintain the boiler water concentration at as low a value as was considered desirable. The following figures are indicative of the purity of the condensate as usually obtained: Total solids, two parts per million; electrical resistivity, 1,000,000 ohms per cm.-cube.

While the dip cells used in determining the electrical resistance of the condensate are subject to erratic behavior at times, the electrical resistance characteristic has been of great help in showing relative performance, because of the rapid change in resistance for a small change in the amount of leakage. Only one leak of consequence has shown up, this one apparently being due to a condenser tube not being rolled in at one end, the flare serving to keep the leakage down for a long time.

The circulating pumps originally furnished required too much power because of the water quantity pumped exceeding the design value and, in order to lessen the load on the motors, it was decided to turn down the impellers.

One trouble which has been had with the steam-jet air pump intercondenser has been the erosion of tubes from the discharge of steam from the pipes used to vent some of the bleeder heaters. Some tubes were removed and a baffle installed to decrease the velocity of the steam hitting the tubes.

The difficulties experienced with the closed bleeder heaters has been confined mainly to those under boiler feed pressure, the most annoying one being the leaking of gasketed joints. Some of this was a result of poor machining. Remachining and the use of different gasket material have eliminated this annoyance almost entirely. One other source of annoyance has been the leaking of a porous, cast-steel water box, which is to be replaced by the manufacturer. The eighth-stage bleeder heater is of the deaërating type and has given no operating troubles. It has delivered water having less than 0.05 cu.cm. per liter of oxygen.

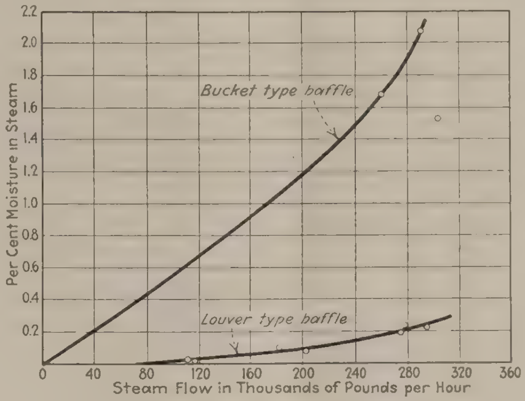
As originally furnished, the evaporator, while its capacity was all that was expected, did not produce a distillate measuring up to the standard required. Considerable experimental work was required before this standard was attained. We were fortunate during this time in having a boiler operating in the old plant supplying steam for heating purposes. Thus, the heating boiler acted as an evaporator and the heating system as an evaporator condenser. The quality of the water obtained in this manner was good and the amount was great enough for make-up purposes. The changes in the design of the evaporator were completed at about the time that the heating season ended. The evaporator is now producing water of the following quality: Total solids, 3.4 parts per million; electrical resistivity, 227,000 ohms per cm.-cube.

With low condenser leakage and water of this quality we have been able not only to hold the boiler water concentration to a low figure but have not been required to blow down the boilers at all on account of concentration, the concentration not having exceeded 500 parts per million.

While the boiler feed pumps are boiler auxiliaries, we are treating them under the head of turbine room equipment, since they are actually in the turbine room and are connected in between the low- and high-pressure bleeder heaters. The motor-driven boiler feed pumps have given but little trouble structurally. On one occasion there was a cessation of pumping, which appeared to be due to vapor binding. This was ascribed to hot water discharged from the evaporator condenser drip pump being fed to the suction side of the boiler feed pump. While there was an economic advantage to the scheme from the standpoint of heat efficiency, it was considered to be outweighed by the demand for safe operation and, accordingly, this water was delivered to the eighth-stage heater. Since then no further trouble of this nature has occurred. A shifting of the impellers and balancing drum occurred on the emergency steam-driven boiler feed pump. This was apparently due to the wearing sleeves turning enough to allow the shift to take place. When repairs were made these sleeves were driven up hard and locked so that this trouble is not expected to occur again.

### Over-All Performance

Whereas the plant delivered power to the bus for the first time on Jan. 4, 1927, the amount of generation for the first three months was comparatively small, because of the decision to concentrate attention on those details which most affected the dependable operation of the plant.



*Effect of changing baffles in steam drum*

Two curves are shown, one of which is that of the predicted performance of the plant in B.t.u. required per net kilowatt-hour of station sendout plotted against weekly load factor in per cent; the other curve is that of the weekly performance in B.t.u. actually used, plotted in the same manner.

### Conclusions

From this outline it is apparent that the plant has been subject to the usual minor changes and adjustments during the initial period of service. None of the troubles experienced were insurmountable and can all be traced to the fact that most of the equipment affected was of the largest sizes that were obtainable, operating in many instances at rather high capacities. This introduced some problems that were entirely new, it being necessary for the manufacturers supplying equipment to do a certain amount of development after their apparatus was placed in service. While such a procedure is necessarily slow, it is felt that the manufacturers affected have made a very satisfactory record in solving their individual problems and in making necessary changes and connections.

The actual performance has approached fairly close to the anticipated, and it is apparent that, when the air heater performance is improved and the effect of the recent increase in steam temperature is realized, the anticipated performance will at least be met and possibly slightly bettered.

# Data on 100,000,000-Kw.-Hr. Systems

### "Electrical World" shows United States has 124 systems each with annual output exceeding 100,000,000 kw.-hr. They generated 64,380,010,246 kw.-hr. in 1927

GROWTH in output of individual companies, a continuation of the process of consolidation of smaller units or groups into larger systems, a rising percentage of the nation's output from these larger systems, and an increase in energy generated per unit of installation are revealed by a comparison of the returns from the annual surveys of systems with more than 100,000,000 kw.-hr. output annually made by the ELECTRICAL WORLD. Details to the extent of about 7,200 items are given in the supplement to the present issue. The results are briefly summarized in the tables on this page.

Of the large light and power systems on the North American continent, 124 are in the United States, fifteen in Canada, and two in Mexico. In addition, fourteen railway systems fall, by virtue of their size, into the same classification. The 124 first mentioned operated 1,423 plants with a total rating of 24,275,311 kva., divided into 17,255,891 kva. in fuel-burning plants and 7,019,420 kva. hydro-electric. These plants generated 64,380,010,246 kw.-hr. during the year; 9,227,208,954 kw.-hr. was added by purchase, making an aggregate output of 73,607,219,200 kw.-hr. The energy generated by all electric light and power plants was, according to the latest revision, 74,753,227,000 kw.-hr. The present survey, therefore, accounts for 86.2 per cent of that total; the aggregate output, including purchase, is almost equivalent to the energy generated by the entire industry, though it must be noted that this aggregate necessarily involves duplication because of resales.

In 1926 the major companies generated 58,073,674,401 kw.-hr. in plants aggregating 22,559,063 kva.* The kilowatt-hour increase is about 11 per cent, and the energy generated per kilovolt-ampere rose from 2,570 to 2,610 kw.-hr.

For the first time a decrease is noted in the number of systems, from 126 in 1926 to 124 in 1927, notwithstanding the addition of ten new names for which no comparable earlier figures could be published, as well as several other cases where a new name could be more or less closely identified with properties previously listed. These additions were more than balanced by absorptions, consolidations and eliminations made to avoid duplication of statistics. The details can be ascertained by reference to the supplement, in particular the copious footnotes and sidenotes there given. It should be noted that in this compilation, as in earlier ones, a system may consist of more than one company provided all are operated as a single physical unit under a common management. Thus the trend toward co-ordinated operation, often followed later by actual financial amalgamations, is reflected in the data showing fewer but larger systems.

The number of systems with more than 1,000,000,000 kw.-hr. output has risen to 21, three more than in the preceding year. Their combined output was 39,671,078,953 kw.-hr., or considerably greater than that of all the rest put together. The leaders, in order, are the Buffalo, Niagara & Eastern system, the Commonwealth Edison of

---

*This is 500,000 kva. lower than the figure published in the issue of April 30, 1927, the Mohawk-Hudson system having been incorrectly credited with 711,600 instead of 211,600 kva. in hydro.

*Table I—Generator Rating and Output of Systems Reporting More Than 100,000,000 Kw.-Hr. During 1927*

(Summary of detailed tabulation in the supplement to this issue of the ELECTRICAL WORLD)

| | | Number of Generating Plants and Generator Rating | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | All Plants | | Fuel Burning | | Hydro-Electric | | | | |
| Section | Number of Companies or Systems | No. | Rating Kva. | No. | Rating Kva. | No. | Rating Kva. | Energy Generated, Kw.-Hr. | Energy Purchased, Kw.-Hr. | Total Energy Output, Kw.-Hr. |
| *United States* | 124 | 1,423 | 24,275,311 | 801 | 17,255,891 | 622 | 7,019,420 | 64,380,010,246 | 9,227,208,954 | 73,607,219,200 |
| New England | 14 | 79 | 1,718,644 | 29 | 1,365,254 | 50 | 353,390 | 3,484,486,229 | 633,510,195 | 4,117,996,424 |

*To avoid misleading totals, approximate allocations have been made of sales of several companies which reported combined figures for more than one class under a single head. In a few instances sufficient information was not available to permit the making of reasonably close approximations. These are summed up in the column "Unsegregated Output."

Chicago, which has the distinction of alone reporting more than 1,000,000 kw. in plant, and the Edison-United of New York, which is also next in order as to plant, with 972,225 kw.

Power sales account for about 33,698,000,000 kw.-hr., nearly 46 per cent of the total output and more than three times the sales directly for residential and commercial lighting. In addition, more than 2,090,000,000 kw.-hr. is sold to municipalities, of which the larger part is no doubt ultimately used for lighting in one form or another. About 10 per cent of the output goes to other public utilities. This item, with its companion "purchased energy," reflects the economies of interconnection and of service from transmission lines replacing previously operated small plants. Railroads are credited with about 5,200,000,000 kw.-hr. This should be augmented by railway loads of unstated magnitude included, in some reports, under other heads, and by energy used by company-owned railways, reported by some companies with intracompany use. These figures unavoidably involve some approximations to allocate energy not completely segregated in the reports, but with this qualification the relationships shown in Table II are believed to be representative.

Losses and energy consumption by the companies themselves vary widely, depending on local conditions. They are, in general, larger in those regions having long transmission distances, either because remote sources of water power are used or because the load centers are widely scattered. The national average of energy thus absorbed is 16.4 per cent of the output.

This year fifteen Canadian companies appear; they generated 11,895,292,334 kw.-hr. and purchased 2,491,824,655 kw.-hr. Last year's list contained but ten, with an output, generated and purchased, of 9,594,982,322 kw.-hr. The gain is due both to marked growth of previously existing systems and the addition of statistics for several not before available. Mexico has two, with a combined output closely approaching 754,000,000 kw.-hr. The heavy predominance of water power in these two countries is noteworthy: Canada has 2,711,284 kva. in hydro, against only 79,750 in fuel plants; Mexico's two companies had 220,660 hydro and 16,500 kva. in fuel-burning plants.

In addition to the light and power systems there are fourteen railways in the 100,000,000 kw.-hr. class. They generated 2,866,100,884 kw.-hr. Adding purchased energy, their total comes to 4,403,351,880 kw.-hr.

# Material Loading Cages Save the Time of Line Crews

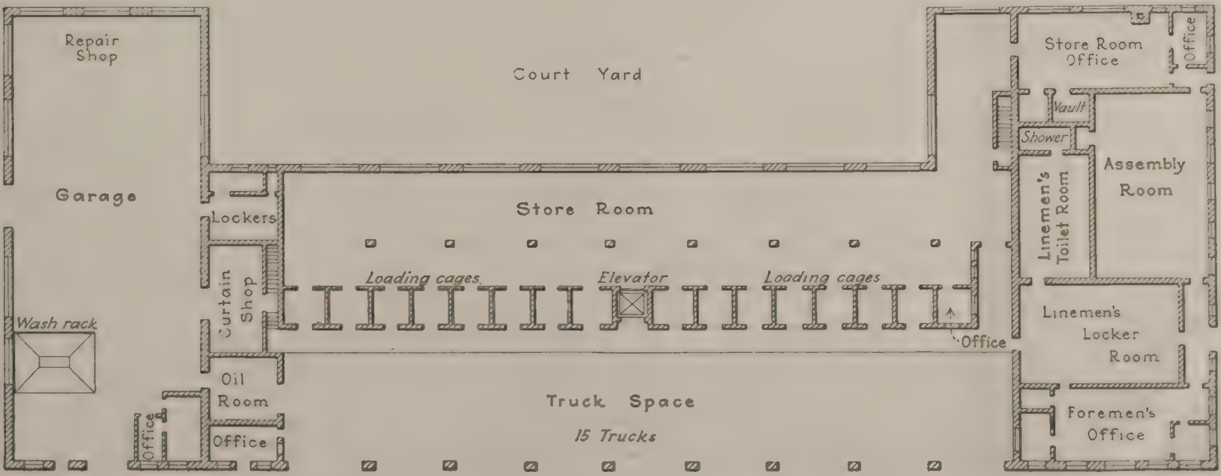
By M. T. Crawford
*Superintendent of Distribution*
*Puget Sound Power & Light Company, Seattle, Wash.*

CONSIDERABLE study has been given to improvement of efficiency in the handling of line construction work by the distribution department of the Puget Sound Power & Light Company. One of the recent steps taken along these lines was the construction of a building carefully designed with a view to facilitating the handling of such work.

*Inclosed concourse and truck-loading platform with doors opening into material cages*

An overhead chain block carrier on I-beam is used for handling transformers and other heavy material.

A reinforced concrete, fireproof building, 115x300 ft., was constructed in Seattle and occupied in 1927 as a headquarters for line construction work within a 30-minute truck-traveling time radius. Under the working rules for employees crews will spend eight hours on the job without payment of overtime under these condi-



*Distribution service building floor plan, showing material cages opening into storeroom as well as onto loading platform* tions. The first unit of this building, constructed at this time, is designed to accommodate a total of fifteen overhead and underground construction crews with their trucks. There was also provided a garage and repair shop for trucks and passenger automobiles, stores and office space, locker, washrooms, an assembly room, etc.

Careful thought was given to the arrangement of the building to provide for the routing of materials and equipment from the time they are received until they go out without confusion or loss of time. In the center front of the building, as will be seen from the accompanying floor plan, a concourse was built and provided with roller metal doors in front and a loading platform behind with standing space for fifteen line trucks. Just across the loading platform and immediately opposite each truck's standing space is a small metal cage which opens also into the storeroom.

This somewhat original feature has been found highly efficient in actual practice as it enables the material men in the general foreman's office to order out a complete bill of material on the day previous to the handling of each job. This batch of material can be put into the cage for the proper crew by the storekeeper and locked up. While the truck is in at night the material brought in from one day's job can be taken out and put in the cage and the material for the next day's work loaded on the truck, so that when the foreman arrives with his crew in the morning the truck is loaded and ready to go.

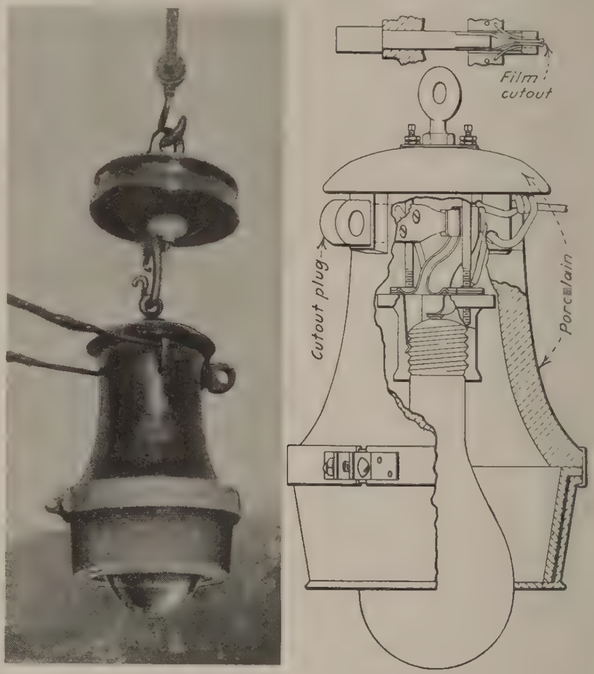
An indication of the economy which has resulted from these improved facilities may be obtained by comparing the actual efficiencies on line construction work during the last six months of 1927, when the new building was in use, with the same period in 1926, when an equally heavy volume of work was handled by the same crews out of headquarters in an old carhouse. This company has for years kept a monthly record of the number of work units completed by line crews from each headquarters. The work unit used consists of such items as a pole set, a transformer hung, etc., selected as nearly as possible to represent an equal amount of labor. While having no exact absolute value, they are very useful for comparative purposes, particularly in checking up on number of men employed and equipment operated in proportion to volume of work done at various times.

During the last six months of 1926 in the old headquarters an average of 47 units per man employed per month was maintained. During the same period in 1927 in the new building, with the improved facilities, an average of 53 work units per man employed per month was recorded. An average of 225 men were employed on line construction at this point, and the 12 per cent improved efficiency indicated from the above record resulted in a substantial saving in the cost of work. A part of this saving, however, was returned to the men, as the company pays a monthly bonus to the crew foremen and material men which is proportional to the record of work units per man employed, and the wage scale itself is also adjusted periodically on a merit rating basis. As a conservative estimate the net savings to the company, after allowing for this, is on the order of $2,250 per month during periods of heavy construction.

Other features of the new service building are a garage and repair shop at one end of the building equipped to handle approximately 150 trucks and passenger automobiles, a full basement accessible from the rear by an inclined driveway across the courtyard, storage space for automobiles and certain infrequently used tools and equipment, a testing and inspection room where distribution transformers are received, tested, repaired and issued. One end of the basement, together with the center part of the main floor, is occupied by the stores division.

## A Simplified Street-Hood

FINDING by experience that many radio interferences could be traced directly to loose screw and friction contacts in series street-hoods, the Dallas (Tex.) Power & Light Company took the bull by the horns and designed a hood that apparently will reduce such interferences to the minimum. In the ordinary type of hood there may be as many as twenty or more screw and friction contacts, each one a potential broadcasting station. The new hood contains only two contacts that are not solid and permanent—those between socket and lamp base. Also, the new hood has a porcelain cap and body assembly, thus eliminating the iron housing that is so susceptible to rust.



*Porcelain-body street-hood equipped with refractor*

The common type of series hood includes a removable lamp socket that is provided with flat spring contact terminals, between which the film cutout is placed. These terminals push into and separate the two sides of a clip which is in series with the line. There are thus at least four purely friction contacts in the ordinary hood, and in potentiality for radio trouble to these must be added the numerous other contacts held down with screws.

In the Dallas type of hood the film cutout is carried between spring fingers mounted on the end of an insulating plug that is inserted in the hood just below the cap. The sides of the clip into which cutout fingers enter are integral with the contacts of the socket, which is mounted permanently in the hood. A pair of lead wires are soldered to the contact pieces and are brought out of the hood for connection into the series circuit. The design and appearance of the new hood are shown in the accompanying illustrations.

# Let Private Enterprise Live![*]

### Entrance of government into power industry would menace private initiative and endanger the present source of capital

By MATTHEW S. SLOAN
*President Brooklyn Edison Company*

THE original electric company had a capitalization of a million dollars. The electrical industry today has a capitalization of approximately nine billion dollars. Those figures, thus set in contrast, will perhaps measure for you the growth and development of the industry as clearly and forcefully as anything that could be said about it. Approximately nine billion dollars invested in buildings and lands, machinery and equipment necessary to produce and supply the electrical service for the use of this nation—the service which takes the burden of toil off the back of the housewife and makes homes better places to live in and increases the productivity of the industrial worker and gives him the fattest pay envelope in the world! Add to that, please, the fact that this power and light industry is required to raise about a billion dollars a year of new capital to supply more and better service facilities so that it may not fall behind the needs of the nation. That capital is obtained, because:

First—The business is sound.

Second—The business is growing rapidly, and is progressive and progressing in all its phases.

Third—The business is keenly sensible of its duties as a public servant and responsive to public sentiment regarding its policies and practices.

Fourth—The business is supervised and regulated by public agencies, usually state officials, as to its standards of service, its accounting, its capitalization and the rates it is permitted to charge.

Public utilities are now the largest customers in the money market, and the power and light branch of the utility family requires more new capital than any other. Investors in the securities of the companies are the great insurance companies, savings banks—the Legislature of New York State recently passed a law permitting such investment, making the nineteenth state to do so—colleges and universities, trust funds, and customers of the companies. Since 1914 more than thirteen million shares of stock have been sold by the companies under the customer-ownership plan, providing more than a billion one hundred million dollars of new capital for carrying on the work of these utilities.

The money invested in the electrical industry has been put to good use. It has provided this country with electrical service which is surpassed nowhere in the world. It has supplied the country with the greatest electrical generating capacity for its homes and work-places, which use almost as much energy in a year as all the rest of the world. It has enabled the managements of the utility companies to experiment and to improve their machinery and their technique, scrapping machinery with seeming ruthlessness in the interest of efficiency and economy. building new lines, higher-voltage lines, interconnecting them to make more certain of freedom from interruptions of service and to put the burden of the load on the most efficient generating plants. Thus the capital obtained has enabled the industry to attain lower costs in the face of higher prices it must pay, and as a result there has been, over a period of years, a reduction in the average price of the electricity used by the public.

> *"President Coolidge said not so long ago that once government embarked in business it must become a monopoly in that business. That assuredly is the prospect in this instance. Put government-raised capital into the power and light business, as is now proposed, and you shut private capital out. You serve notice on the electrical industry that it is in competition with the great federal government itself."*

The National Industrial Conference Board reported recently that while the cost of living in July of last year was 62 per cent higher than in 1914, the price of electricity was 13 per cent lower than in 1914. These figures were arrived at after a survey covering 143 cities having a combined population of more than thirty-two million people.

The industry as it is today is the product of American initiative and enterprise—supervised and regulated by public authorities as it should be, controlled by laws and their official administrators as it should be, because it is an industry affected with a public interest, but nevertheless having opportunity, under our American system, to work out its destiny for itself and for the benefit of the public whose servant it is. We of the industry believe the record has been a good one. We are proud of it.

This industry, however, faces new conditions. We deem them a menace to the industry, but, above all beyond that, to the system under which America has grown great. Legislation is pending in Congress which would put the federal government into the electric power and light business. There are two bills for the utilization of the government's war enterprise at Muscle Shoals. They differ materially in their provisions, but the net of both is to seek to embark the government in the manufacture of fertilizer and in the production of power, competing in both lines with the capital of its citizens invested in these businesses. There is also the so-called Boulder Dam bill, termed by its advocates a measure for flood relief and for conservation, termed by its opponents—and some of them who are fighting it in Congress are no part of the electrical industry—an attempt to put the government into the power business under the guise of a public improvement. Then there are other bills and other proposals not yet brought into the form of legislation which would put the government into the power business in other sections of the country.

---

[*] *From a recent address before the Bond Club in Newark.*

The electrical industry has been criticised as selfish (in fact, that is one of the mildest things said about it) because it is opposed to such legislation and such proposals. Perhaps it is. But what is the industry? It is a good deal more than the men who are on the utility payrolls, who happen by virtue of their positions as officers of the utility companies to express that opposition. It includes the investors, individual and institutional, who have put up the nine billion dollars of their savings and now are threatened with government capital in competition. Are these people selfish if they oppose having the government raise funds from them to put to work against their present investments? If they are, it's a trait which will not be found lacking in the very great majority of the people.

There is here no war emergency such as impelled the government to take over the operation of the railroads and go into the shipping business. There is no condition or situation in respect of utilization of Muscle Shoals or prevention of floods on the Colorado which could not be met without putting the government into the electrical business. Why seek to do it, unless there is an intent to change the entire policy of our country respecting government in business?

President Coolidge said not so long ago that once government embarked in business it must become a monopoly in that business. That, assuredly, is the prospect in this instance. Put government-raised capital into the power and light business, as is now proposed, and you shut private capital out. You serve notice on the electrical industry that it is in competition with the great federal government itself. You serve notice on people with money to invest that they will be in competition with government, with its power to tax and to confiscate. Will they do it? Is it good sense to expect that they will be willing to do it?

### End of Private Initiative

Creating a government power monopoly, however, would be merely the beginning. Do that, and you notify American business and the American people that the door of opportunity has begun to shut against them. You tell them that one business—a great, vital business, a key industry—has been taken out of the realm of individual opportunity and has been socialized. What will that do to our American spirit? What will it do to American business—not alone that one which happens to be on the firing line now, but to all business?

Perhaps I am unable to see this situation entirely clearly, because it is the business to which I have devoted my life which is menaced. It seems to me, however, that no one thing more far reaching in its effects could be brought about. The spirit of man cannot be crushed by obstacles, so long as there remains the opportunity for achievement. But if the opportunity itself be narrowed —if there exists the prospect that it may become still narrower—the inducement to struggle is stifled at birth.

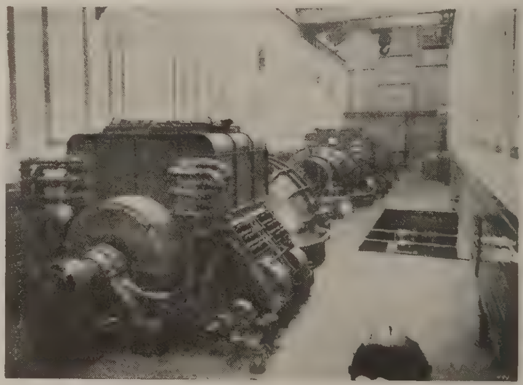
The situation I have been discussing presents something for our consideration far bigger and broader than the future of the electrical industry, important as that may be to our country. There may seem to be in these bills merely a matter of methods and their justification at the moment—a question of expediency. That is the least part of the situation. There is involved in them a vital question of national policy, settlement of which must create a precedent of lasting import. Either this country is to remain what it has been—a land in which business is to be conducted by the people, and the people are to be economically free—or it is to be changed to something else, something not contemplated by the founders of our government. All business is to remain free from government competition and government absorption, or we are to find ourselves on the road to socialization of all business, which means destruction of individual rights, liberty and happiness as we have visioned and experienced them.

Our system of business and government, each operating in its own field, has been proved for nearly a century and a half. It has worked. Business has not been perfect, neither has government, because each can be no better than the people who are engaged in administering its affairs and human nature has not yet reached perfection. Yet the good in government and the good in business have vastly outweighed the bad, and in each field there has been advancement of ideas, advancement of methods and an attainment of results signally beneficial to our people.

The spirit of our nation and the social-economic system in which that spirit finds expression call forth and stimulate the good and discourage its opposite qualities. That, I repeat, our experience has proved. When that spirit is stifled and that system is altered we shall cease to be America, the land of opportunity.

---

## Two 60,000-Kw. Turbo-Generators in New East River Station



STEAM is generated at 375 lb. pressure and 700 deg. F. in six cross-drum boilers in the new East River station of the New York Edison Company. Combustion chambers are entirely inclosed by water-cooled walls of the Murray fin-tube type, no brickwork or refractories being used. It is the first power station to burn pulverized coal on a large scale in New York City.

The air coolers are mounted above the generators and consist of nests of spiral-finned tubes. Each cooler is served by two motor-driven blowers supplying 110,000 cu.ft. of air per minute in a closed system. Cooling water is taken from the condenser circulating system.

# Patent Pools and Anti-Trust Laws

By David L. Podell and Benjamin S. Kirsh
*Members of the New York City Bar*

*The industrial and social value of patent interchange and its relation to the anti-trust laws and patent rights are outlined in this article by Messrs. Podell and Kirsh, which appeared in the American Bar Association Journal. A series of patent agreements among gasoline cracking refineries, made as the result of a conflict of patents, recently was held to be reasonable and lawful and was not "in restraint of trade." The whole argument for patent interchange becomes valid only when there is a need for it as in the gasoline case. Where the great majority of patents covering any product are held by one company there may cease to be any need for an interchange of patents covering that product.*

THE issuance of a large number of inter-related patents and their distribution among various independent owners in the same industry has presented forcibly the necessity of patent co-operation. An inquiry into the legal status of co-operative interchange presents the problem of the extent to which the rights acquired under the patent laws run parallel to or conflict with the liabilities, both civil and criminal, arising from a violation of the anti-trust laws.

In the annual reports of the Attorneys-General of the United States for the years 1924 and 1925 the application of the Sherman law to the acquisition and pooling of patents is noted as one of the major problems of anti-trust enforcement. It "involves the application of the anti-trust law to restraints of trade based upon the acquisition or pooling of competitive patents. The anti-trust law and the patent law have different and to some extent conflicting purposes. Combinations by means of cross-licenses under patents are now frequently encountered." It is to be observed that the Supreme Court in formulating the policy of the law has taken occasion in one important line of cases first to announce one rule of law and then to reverse its former judgment by adopting what had been the dissenting view. This was done, furthermore, over the protest of some of the justices, in whose opinion the law had already acquired the attributes of a rule of property. Of the entire field, it has been stated by an analytical writer that "few problems have given rise to more confusing diversity of judicial opinion."

Perhaps it is not amiss to point out that the term "pool" is itself unfortunate in view of its inevitable association, in our industrial history, with some of the most oppressive combinations in restraint of trade, which directly led to the formation of our anti-trust policy. For this reason, its use has been avoided, even by stanch advocates of patent interchange. By the "pooling of patents," however, we shall rather refer to the co-operative interchange of patent rights, centralized pursuant to an agreement, including the covenants and restrictions with which one can find them usually accompanied. By means of reciprocal privileges, mutually granted, the licensee gains by agreement what the patent law otherwise prohibits. The meaning of the phrase "restraint of trade," as used in the Sherman act, has been settled since the authoritative definition in the Standard oil case to refer solely to those restrictions which are undue and unreasonable and injurious to the public welfare.

No discussion of the legal questions involved can be thoroughly understood without some knowledge of the value to business and society of the co-operative interchange of patent rights. From the experience of American industry a mass of information lies available to the student of the subject. This is evident by reference to the cross-licensing arrangement in the automobile and aircraft industries and the recent resolution of the National Electrical Manufacturers' Association. One of the underlying reasons for the formation of an interchange of patent rights lies in the practical necessity to adjust infringement litigation where there is a claim of overlapping patents. No royalties, however great, would suffice to pay the tribute which protracted and costly patent litigation exacts. An inflated selling price the commodity ensues. There is a shift, by incidence, of the price of litigation to the consumer. It is, therefore, but prudent and economical business policy to compromise what otherwise would entail enormous expenditures and lead to a diminution of sales.

Fear of infringement suits, injunctions and decrees for heavy damages has dissuaded manufacturers from making expenditures to improve their plants and has resulted in enhancement of prices to secure them against the risk of operation under doubtful patents. Thus it has been said with reference to the cross-licensing agreement in the aircraft industry that it is "a practical business arrangement to do away with litigation over patents and permit the members to build planes rather than try lawsuits against each other. Moreover, a practical consideration arising from our heavily burdened court calendars is that the original trial of a patent suit is not generally reached, in many districts, before two years, and that before a final adjudication can be reached some four to seven years may elapse, if both parties insist upon exhausting their remedies. Even the payment of royalties under a cross-licensing agreement becomes, therefore, an economically sound business arrangement whereby, in effect, an insurance policy is taken out as security from attack, at a cost known in advance.

### INDUSTRY GAINS THE DIRECT BENEFITS

From a purely economic viewpoint a mere dedication of reciprocal non-exclusive licenses can be subjected to no reasonable criticism. The industry at large, which is judged by the output of its entire production, gains the direct benefits. There is an increased good will arising from greater confidence in the minds of consumers. Therefore, every product can embody the latest and most aproved engineering ideas and still retain for each manufacturer individuality of design, which is his distinguishing selling feature. The raising of standards follows as a natural consequence. Another important advantage of cross-licensing is in its value to each individual party to the agreement in securing for himself the results of a large volume of development research and the accumulated practical experience embodied in the patents of his cross-licenses. A company putting in five patents may acquire the use of 125 in return, an advantage far outweighing the exploitation of its own inventions.

It has been demonstrated by the recorded experience in the automobile industry that such agreements give an impetus to further invention. Every company is anxious to have the distinction that its product is first to embody the latest improvements in the industry. The automobile industry has found from its experience that for various reasons, such as the skepticism of other members with reference to the value of new patents, the company which secures a patent and applies it immediately to the betterment of its product has at least a year's start over its competitors. A patent owned or controlled by one member of an industry may be useless in itself, yet extremely valuable when combined in use with other patents owned by his competitors. By breaking up what has been aptly termed the "congestion of patents," every patent owner is free to improve his product. Without the privilege of making use of the numerous improvement patents, the patentee finds himself in the position of the owner of a key plot who must pay a stipend to assemble contiguous plottage. Again, the psychological factor in industry is extremely improved when its members can feel that they are united with a single purpose of bettering their product through the common utilization of technical knowledge.

### THE ANTI-TRUST LAWS AND PATENT RIGHTS

Regarding the anti-trust laws and patent rights, it is sufficient to indicate that the decided cases apply various legal tests. The chief factors thus far discussed by the courts involve the effect of the combination, its extent, its nature, the methods employed, the intent of the parties and the particular facts in the industry. It is further to be borne in mind that each case arising under the Sherman act must be determined upon a consideration of the particular facts discussed by the record. Justice Brandeis expresses the spirit of the law in the Board of Trade of Chicago against the United States: "But the legality of an agreement or regulation cannot be determined by so simple a test as whether it restrains competition. Every agreement concerning trade, every regulation of trade restrains. . . . The true test of legality is whether the restraint imposed is such as merely regulates and perhaps thereby promotes competition, or whether it is such as may suppress or even destroy competition. . . . The history of the restraint, the evil believed to exist, the reason for adopting the particular remedy, the purpose or end sought to be attained are all relevant facts. This is not because a good intention will save an otherwise objectionable regulation, or the reverse, but because knowledge of intent may help the court to interpret facts and to predict consequences."

Several questions involving the legal consequences of a combination of patentees have not yet been squarely determined by the Supreme Court. One involves the effect of an agreement among various patentees allowing a stated sum, jointly fixed, to be paid as royalties to a patentee for the use of his invention. Another is the effect of arbitration clauses by which compensation for the use of patents is determined by arbitrators as each case arises. There is, however, the recorded authority of the Department of Justice, approving, as not violative of the anti-trust laws, such a clause, found in the Manufacturers' Aircraft Association agreement. The fundamental question of law reduces itself to the proposition that where the purpose and effect of such royalty agreements are merely to secure a fair and just compensation for the use of the patents and are not unduly restrictive of free competition no violation of law occurs. If the royalty charged is small, in comparison with the total cost of the product, there does not seem to be a substantial relation between the royalty and the ultimate selling price. In other words, it is ordinarily too remote in the chain of causation to adjudge that the royalty, which is only a small fraction of the ultimate selling price, is to be deemed a controlling factor in a joint effort on the part of several patentees to regulate the price.

### ADVANTAGES OF PATENT INTERCHANGE

Viewing its underlying principles, we are led to the conclusion that it is nothing more than a scientific and intelligent co-operation of creative or inventive thought, much akin to a bureau for scientific research. In principle, it is a democratization of ownership or interest in an original or creative idea, or group of ideas, a clearing house for the advancement of invention. Indirectly, it is a dedication to society of the aggregate of such scientific data. Where the patent law would grant exclusive ownership in one, the patent pool extends it to many. That its tendency would be to improve or perfect the product has been confirmed by experience.

Patent interchange tends likewise toward standardization of the product, reduced cost of production, elimination of the enormous waste of litigation and indeed yields; in short, the advantages to the public of a better commodity at a cheaper price. Again we are confronted with the dangers of abuse of concentrated power, either by joint price fixing, boycott against competitors or other illegal restraints, by the combined patentees. There is ample power in the government to cope with such problems as they arise in a given case. That patent co-operation is capable of abuse is doubtless true, but this possibility is inherent in all joint effort. Where it is present it can be detected and penalized in accordance with the provisions of the statutes. A plan which secures to the patentee a just compensation for his novel idea and bestows upon the public the benefits of progress serves a beneficial and commendable purpose. This underlying principle seems to be in harmony rather than in conflict with the anti-trust laws.

# "Average Use" Misleading in Analyzing Promotional Rates

THE importance of drawing conclusions from thorough analysis of individual use rather than basing them on application of average figures, when rates of a promotional type are being considered, was emphasized in a recent hearing before the Massachusetts Department of Public Utilities by Vernon Tallman, manager commercial and industrial department, Charles H. Tenney & Company, Boston. He pointed out that the results of making comparisons based on "average use" are not only misleading but far from accurate.

The application of a proposed room rate schedule to the residence service of the Malden Electric Company was under consideration. By this schedule the customer would pay for service under the following rate:

| Per Room Per Month | Cents Per Kilowatt-Hour |
|---|---|
| First 3 kw.-hr. | at 10 |
| Next 5 kw.-hr. | at 7½ |
| Excess over 8 kw.-hr. | at 4 |

The company claimed that this rate would have reduced the charges to its residential customers more than $68,000 per year. This reduction was based upon a detailed study of a representative cross-section of all the company's accounts and based on actual bill computations.

A calculation of the reduction on the basis of the "average use" customer indicated a reduction of only about $23,000. The error introduced by consideration of the "average use" is, therefore, $45,000 in this particular case, and the reduction under the "average use" basis is only 34 per cent of the true reduction. Companies which have been in the habit of using the "average use" and estimating reductions based upon it may find that their actual reductions are three times as much if they analyze the bills in detail. This is a pitfall to be carefully guarded against, as is well recognized by experienced rate engineers.

By way of illustration, Mr. Tallman presented a comparison of the two methods of calculation in a simple case of five customers having six rooms each:

| Customers | Total Kw.-Hr. |
|---|---|
| Four used 20 kw.-hr. per month each, or | 80 |
| One used 70 kw.-hr. per month, or | 70 |
| Total used by five customers | 150 |
| Average per customer | 30 |

Bill for average customer calculated on old and new rates:

| | |
|---|---|
| **Old Rate** | |
| 15 kw.-hr. at 10½ cents = | $1.57 |
| 15 kw.-hr. at 8 cents = | 1.20 |
| 30 kw.-hr. | $2.77 |
| **New Rate** | |
| First 3 per room 18 kw.-hr. at 10 cents = | $1.80 |
| Next 5 per room 12 kw.-hr. at 7½ cents = | 0.90 |
| 30 kw.-hr. | $2.70 |

A saving of 7 cents per month per customer or 35 cents per month for the group.

Bills for actual customers calculated on old and new rates:

| | | |
|---|---|---|
| **Old Rate** | | |
| 15 kw.-hr. at 10½ cents = | $1.57 | |
| 5 kw.-hr. at 8 cents = | 0.40 | |
| 20 kw.-hr. | | |
| Four customers at | $1.97 or | $7.88 |
| **New Rate** | | |
| 18 kw.-hr. at 10 cents = | $1.80 | |
| 2 kw.-hr. at 7½ cents = | 0.15 | |
| 20 kw.-hr. | | |
| Four customers at | $1.95 or | $7.80 |
| 15 kw.-hr. at 10½ cents = | $1.57 | |
| 55 kw.-hr. at 8 cents = | 4.40 | |
| 70 kw.-hr. | | |
| One customer at | $5.97 | $5.97 |
| Total for group | | $13.85 |
| Average rate | | 9.2 cents per kilowatt-hour |
| First 3 per room 18 kw.-hr. at 10 cents = | $1.80 | |
| Next 5 per room 30 kw.-hr. at 7½ cents = | 2.25 | |
| Excess 22 kw.-hr. at 4 cents = | 0.88 | |
| 70 kw.-hr. | | |
| One customer at | $4.93 | $4.93 |
| Total for group | | $12.73 |
| Average rate | | 8.5 cents per kilowatt-hour |

---

# 90,000-Kw. Generator Shipped Completely Wound

THE new turbo-generator unit of 90,000 kw. capacity designed for the Long Beach plant of the Southern California Edison Company is unusual because of its high rating and for the use of a terminal voltage of 16,500. The turbine is a single-shaft, tandem-compound unit. The high-pressure cylinder contains an eighteen-stage rotor and the low-pressure cylinder a three-stage double-flow rotor. Steam is used at 400 lb. gage and 725 deg. F. total temperature.

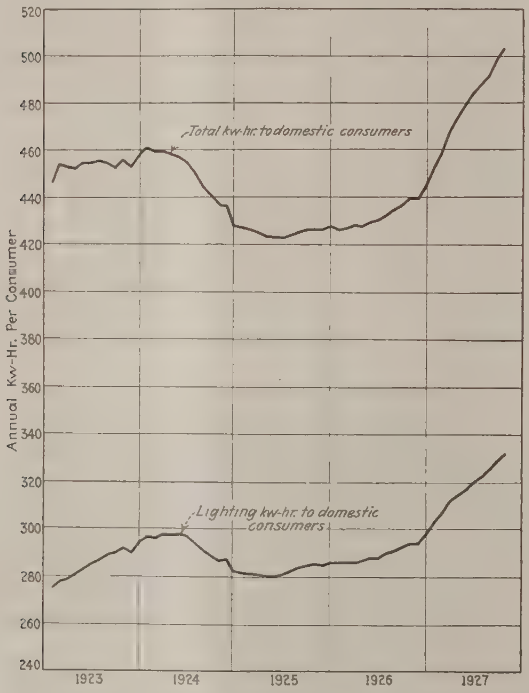
The generator was shipped completely wound, an accomplishment made possible by the welded construction of the unit. It is the product of the General Electric Company and is shown in the process of shop testing.

# 1,331 Ranges Sold in Seven Weeks' Campaign

### Southern California Edison Company has most successful campaign in its history. Dealer co-operation and old-range allowance were factors

By R. G. Kenyon
*Assistant Advertising Manager Southern California Edison Company, Los Angeles, Calif.*

MERCHANDISING accomplishments of the Southern California Edison Company for 1927 under the supervision of W. L. Frost, general commercial manager, culminated in the most successful major appliance campaign of the company's history—a seven weeks' Hotpoint range campaign. The actual ranges sold, 1,331, were more than double the quota of 600 ranges set for the entire system. Of the ranges sold, 1,003 were sold by the Edison company merchandising organization; the balance, or 328 ranges, were sold through electrical contractors or dealers. Every dealer and contractor in the territory was invited to take advantage of the public desire to buy ranges which would be created by the intensive campaign carried on by the power company. The record of 328 ranges sold through dealers and contractors amply proves that the contractor-dealer is a very valuable potential outlet for electrical merchandise when the proper co-operative help is given.



*Kilowatt-hour sales to domestic customers show effect of increased sales activities*

In this campaign ideas found profitable in previous range campaigns were adopted. Special terms of $10 down and the balance in six, twelve or eighteen months were offered. Three modes of advertising were used—window trims, newspapers and direct mail. Window-trim material was furnished all district offices and suggestions and helps for the proper use of this material were offered them. In the newspaper campaign every one of the 160 newspapers in the territory served by the company carried at least one ad every two weeks and in the larger papers one ad a week. In addition to carrying the name of the Southern California Edison Company in all cases, the dealer's name in the local district was included in the advertisement. In the direct-mail advertising a selected list of 40,000 names was circularized with a four-piece mailing campaign. The three first pieces consisted of combination broadsides and letters. The fourth piece was a return government postcard to impress upon the prospect the necessity of immediate action to benefit by the campaign. All mailings carried with them return postcards asking for information.

In the advertising copy stress was placed upon the fact that range users enjoyed a very low rate for all electricity used. In addition each piece of advertising matter carried a line telling the reader that his own electrical dealer was in position to offer the same terms of sale as the power company.

To stimulate interest in the campaign on the part of employees bonuses were offered by the company. All employees turning in prospects which developed into sales were paid a bonus of $2.50 for each prospect. In addition to this company-paid bonus, many of the salesmen added a like amount on their own account. As a consequence 374 sales were directly traceable to employee leads.

### Old Range Allowance

Departing radically from all previous sales policies, a salvage allowance was offered on consumers' old cooking equipment. Salesmen were empowered to take in trade the old range of the prospect, irrespective of make or condition, for a sum not to exceed 10 per cent of the purchase price of the new range. About 50 per cent of all sales made by the Edison sales organization were made with this trade-in allowance, a total of 484 sales out of 1,003 being thus made. In addition to this salvage allowance each Hotpoint range carried with it a premium of an Edison waffle iron and tray. To establish the real value of the waffle iron and tray it was offered as a small appliance special during the period of the campaign, at a special low price. To carry the message of this special to consumers, 240,000 stuffers were sent out with the monthly bills during the campaign. These stuffers emphasized the waffle iron special, but also carried the story that this waffle iron was obtainable free with a Hotpoint range. The dealers were privileged to make the same trade-in offer on ranges which they sold, except that they were not empowered to give away a waffle iron with ranges other than Hotpoint. The Edison company refunded to the dealer the amount allowed on the old range and also furnished the waffle irons in the case of Hotpoint range sales.

In presenting campaign plans to the Edison sales organization a series of meetings was held throughout the territory. These meetings were addressed by R. W. Turnbull, Pacific Coast sales manager of the Edison Electric Appliance Company; P. H. Booth, southern California representative of the same company; H. C. Rice, merchandising manager of the Southern California Edison Company, and R. G. Kenyon, assistant advertising manager of the same organization. Much of the outstanding success of the campaign has been attributed to the sales talks made by Mr. Turnbull at these meetings.

Since the Southern California Edison Company is primarily interested in increasing the consumption of existing customers, the results shown by the accompanying curves indicate that range campaigns such as this have had a most decided effect in accomplishing desired results. Evidences of the value of the additional sales effort put upon ranges and appliances is brought out by these curves. Both curves cover a period beginning with the first of 1923 and running through to the end of 1927. In the lower curve lighting sales to domestic customers are shown. The upper curve shows total sales to domestic customers. In this compilation all domestic consumption is covered, including lighting, cooking and water heating. It will be seen that from the low ebb of 422 kw.-hr. per customer in 1925 the company has rapidly built up the per customer consumption until it has reached the high figure of 502 at the end of October, 1927. Both curves are built up on the basis of kilowatt-hours per customer for twelve months ending each month.

# Electric Forging of Tappets Proves Successful

By Sam Stites

*Power Engineer Consumers Power Company, Battle Creek, Mich.*

AN INTERESTING application of electric heat has lately been made at the plant of the Rich Steel products Company in connection with the manufacture of tappets for automobile valves. These are usually made from ⅝-in. steel stock formed in an upsetting press. The stock is first cut into 5-in. lengths and partly machined. In the next operation about 2 in. of one end is brought to a red heat and the piece placed in a die. The die is placed in a press and the projecting red-hot end is upset. On the return stroke of the press the die is reversed by the operator and the piece is pressed out by a plunger. Heating prior to upsetting is done by a Berwick heater, made by the American Car & Foundry Company, with slight modifications to adapt it to the tappet job.

In service, the piece to be heated is held in tongs by the operator and inserted between two copper jaws forming one electrode. The second electrode is a solid block of copper pressed by a spring against the end of the stock. A transformer integral with the heater supplies the necessary current. The tappets as turned out by the press are formed to such close limits that little machining is required, and for this reason the stock must not be marred or pitted in heating. When the electric heater was first tried some difficulty arose from imperfect contact, causing burned or pitted spots at the points of contact between the stock and the electrode. This was overcome by slightly rounding the jaws at the contact point and increasing the spring pressure.

EXPERIENCE WITH TAPPET HEATER

| | | |
|---|---|---|
| Diameter of stock | ⅝ in. | |
| Length of part heated | 2 in. | |
| Weight of metal heated | 0.174 lb. per piece | |
| Demand of heater | 15.8 kw. maximum | |
| Power factor of above demand | 96 per cent | |
| | Test No. 1 | Test No. 2 |
| Time, hours (week's production) | 3 | 1 |
| Number of pieces heated | 1,054 | 13,642 |
| Kilowatt-hours used | 40 | 550 |
| Kilowatt-hours per 100 lb | 20.6 | 23.2 |
| Kilowatt-hours per 1,000 pieces | 37.9 | 40.3 |
| Cost, electricity per thousand pieces (at average annual rate) | $0.70 | $0.75 |

Note—Test 2 gave lower efficiency as operator left heat on during mechanical adjustment of press.

The results were such that two more heaters have been ordered, making four in service. Better quality of work has been obtained and the company finds the method more economical than former methods. These units give the power company a load with an annual consumption of 140,000 kw.-hr. and a revenue of about $2,500. Two test runs gave the data shown in the accompanying table.

*Heating tappets electrically cost 70 to 75 cents or less per thousand pieces for energy*

# Changing-Color Floodlighting for Philadelphia

THE color lighting of the exterior of buildings may soon prove to possess valuable possibilities for increasing commercial revenues. An attractive and spectacular development in floodlighting has been incorporated in the exterior illumination of the new home of the Philadelphia Electric Company. Changing colors are projected onto the stepped-back superstructure, upper walls and columns of the new Edison Building. The equipment used for this purpose is mounted close to the surfaces to be illuminated and the lamps are provided with color caps similar to those planned, but never used, for the Tower of Light at the Sesqui-Centennial in Philadelphia. There are 483 floodlights utilizing 500- and 1,000-watt lamps in this installation. The necessary apparatus was supplied and designed by the Pittsburgh Reflector Company, the Ward Leonard Company and the Laco-Phillips Company.

Several years ago illuminating engineers of the Commonwealth Edison Company co-operated with the owners of the McJunkin Building, Chicago, in providing for that structure exterior color illumination. Instead of utilizing wash color, use was made of harmonizing combinations of color to produce artistic effects.

## *Stokers for New Detroit Plant No Reflection on Powdered Fuel*

*To the Editor of the* ELECTRICAL WORLD:

The Detroit Edison Company has just decided to install underfeed stokers for the first six boiler units of its new plant, now in course of construction, which is to be known as Delray power house No. 3. Inasmuch as this company's Trenton Channel plant, which immediately preceded this in construction, is equipped for pulverized fuel burning, the choice of stokers for Delray No. 3 might be misinterpreted as indicating that in the opinion of the company's engineers the stoker method of firing had inherent advantages over the pulverized fuel method. Any such inference would be misleading in the extreme, as other factors must be considered.

It is pertinent to explain that until Trenton Channel was built it had been the Detroit Edison Company's long-established practice in all of its power plants, at Delray, Connors Creek and most recently at Marysville, to employ an underfeed type of stoker well suited to the character of the best coal ordinarily available; a comparatively low-fusing, very high volatile bituminous coal from West Virginia and eastern Kentucky. Long experience with stokers had developed the company's stoker practice to a satisfactorily high standard at the time the Trenton Channel plant was designed. The use of pulverized fuel at Trenton was therefore a new departure in the company's practice. The factor which conclusively determined that departure was the belief, later amply borne out by the result, that with pulverized fuel the plant would very easily adapt itself to minor variations in character of coal without impairment of capacity and with a minimum impairment of efficiency. It was felt highly desirable to have at least one such plant in the system in order to facilitate classifying the incoming coal and if it should ever become necessary to permit favoring the older plants at Delray and Connors Creek in the allocation of the received fuel. The southern site at Trenton Channel and its large trackage for receipt of coal made it particularly suitable as the pulverized coal plant in this set-up. Its projected large share in total output (41 per cent in 1927) would necessarily make it an important factor in the problem of fuel supply.

Trenton Channel, with the last of its complement of six 50,000-kw. turbines now being erected, has justified the decision made at the time its design was fixed. The investment per kilowatt installed is moderate and its operating performance has never fallen below the estimate of efficiency. For more than a year and a half it has consistently bettered that estimate, and there is reasonable expectation of further improvement. Problems incidental to the method of fuel burning have been satisfactorily met; for instance, the problem of substantial reduction of the fine ash carried away by the furnace gases. The Cottrell precipitators, with which all the boilers are now equipped, seem to be entirely practicable pieces of power plant equipment and are catching large quantities of dust, which for the time being is sluiced on to nearby marshy ground.

At Delray the new plant will be handled by the same organization that has superintendence of the two older power houses, Nos. 1 and 2. The management of stokers for high efficiency will be no novelty for that group of men. Estimates of performance and of required investment for the two types of plant (stoker and pulverized fuel) indicate total costs for the Delray location so nearly alike as to suggest the question whether or not the difference is of the same order as the possible errors of estimate. The final decision to install stokers in the first section of plant was determined by a consideration ordinarily too insignificant to become a controlling factor in plant design.

Up to the present time no permanently satisfactory way has been found for disposing of the fine ash produced by pulverized fuel furnaces after it has been caught. At Trenton Channel there are still marshes to be filled in, but there are no longer any such hollows near Delray. Conversely, the sale of stoker cinders from the Delray plant in a local market which it has never been possible to satisfy will earn a credit of something more than 6½ cents per ton of coal burned. These well-burned cinders are used as aggregate for concrete roof and floor slabs, as the body of so-called cinder blocks used in building construction, and in other ways which constitute a demand for cinders all the year around. But nobody wants the fine residuum from pulverized coal fires.

The design of the new Delray boiler furnaces can be easily adapted to pulverized fuel and the plant would accommodate the necessary equipment, but until this particular commercial problem of ash dust disposal is solved the Detroit Edison Company prefers, and will continue the use of, stokers at the Delray plants.

J. W. PARKER,
Vice-President and Chief Engineer.
Detroit Edison Company.

## *Agrees as to the Undesirability of Steaming Timber*

*To the Editor of the* ELECTRICAL WORLD:

I have been much interested in the articles and discussions on the treatment of Southern pine poles and particularly in the discussion of Mr. Wilson in your edition of April 14. I agree thoroughly with him in his opinion as to the undesirability of steaming timber. If the temperature is raised too high the strength of the timber is permanently impaired. If fairly high temperature is not used the so-called steam seasoning is inefficient. Committee 17 of the American Railway Engineering Association, when it offered the new specifications to that association, made no provision for steaming timber and expressed the firm opinion that this method of treatment should not be used except in emergency. As a member of this committee I concurred heartily.

Air seasoning can be successfully practiced in almost any location on the Atlantic and Gulf Coasts if proper care is taken. There has been much timber damaged in this process, but the damage is generally caused by improper methods. An air-seasoned stick can be much more evenly treated. It has greater strength and in every way makes a more desirable pole than a steamed pole. The cost of carrying poles for the required time is not excessive, amounting to not over 10 or 15 cents for a 35-ft. B pole, and this added cost is certainly justified by the greater value of the pole when so treated.

Some other preservatives are coming into use, but they cannot be used except with air-seasoned timber. One of these seems to have great value for pole treatment.

WILLIAM G. ATWOOD,
New York. Consulting Engineer.

# Digest of Electrical Literature

### *Hydro-Electric Development and Steam Equipment*

*Waterwheel Testing and Operating Records of Plant Discharge.*—This serial report of the hydraulic power committee of the N.E.L.A. includes recommendations for the study and use of modern facilities for the measurement of hydro-electric power plant water input and available power. Conditions reported for the industry include: Definite improvements in plant earning capacity; stand-by losses that are often unknown and can be prevented; operating experiences, including methods and apparatus; special use of well-known metering principles, and the practice of including in plant design advance preparation for tests and metering work. The balance sheet idea as applied to power plant operation is explained in detail in connection with the activities of one of the largest of the hydro-electric systems, as is a description of a long-distance recording water level gage utilizing the Selsyn motor principle.—*Serial Report National Electric Light Association,* March, 1928.

*Propeller Turbines as Hydro-Electric Prime Mover.*—H. Pflieger-Haertel.—The utilization of low or medium head water power with Francis type waterwheels leads to low speeds and consequently large generators. The introduction of the propeller turbine was a marked improvement in this respect, since this construction may, according to the author, readily give a specific speed of up to 1,000, or more than twice the value of the Francis turbine. Equipped with three to six vanes, the chief characteristic of the propeller wheel is an open space between vanes, which may be as much as 50 per cent of the vane surface. A special hub construction permits a change of the angle of the vanes to regulate speed or efficiency. During 1927 a total of 100 propeller turbines were installed in Europe.—*Elektrotechnische Zeitschrift,* March 22 and 29, 1928.

### *Units, Measurements and Instruments*

*An Instrument for Measuring Very Small Displacements.*—Juichi Obata.—The construction and application of a new instrument for measuring small displacements or motions and utilizing an electrical circuit are described by the author. In its usual form the instrument consists of a tuned grid circuit, but it is stated by the author that this can easily be changed to the Colpitts-Hartley circuit. The displacement or motion to be measured is made to produce either a change in the capacity of the circuit or a change in the eddy-current loss, and in consequence a corresponding change in the anode current of the thermionic valve. This change in the anode current is measured with a galvanometer, or, if a permanent record is required, an oscillograph may be used. In this instrument the capacity method, as well as the eddy-current method, may be utilized, and the anode current may be balanced or a transformer may be inserted, all the necessary resistances and the transformer constituting a unit.—*Journal of the Institute of Electrical Engineers of Japan,* January, 1928.

*Limits of X-Ray Investigations.*—O. Morgenstern.—To find blowholes or detect a lack of homogeneity in metal castings, porcelain and other solid materials a visual investigation or a photographic record with X-rays is used extensively. The author points out that, beyond a certain thickness of the materials tested, the output of the X-ray tube, the necessary time of exposure and the clearness of the resulting negative are three factors which set a definite upper limit to the usefulness of this process. Tubes of the Coolidge type are available today for 500 watts, 1,400 watts and 5,000 watts input, while tube voltages of as high as 230 kv. can be managed. Aluminum or aluminum alloy castings up to about 12 in. thickness and iron or steel up to 4 in. represent today, and probably for many years to come, the upper limit. A 10 per cent increase in thickness requires for iron and 220-kv. tube voltage a trebling of the exposure.—*Siemens Zeitschrift,* February, 1928.

*The Design of Nomograms.*—L. B. W. Jolley.—The discussion in this article is restricted to a description of one type of diagram, but the elements of design have been thoroughly considered, offering an analysis of the determination on which the whole subject of nomograms rests. The author has analyzed the determinants, has applied the determinants to alignment charts with straight, parallel and curved scales and presents the necessary mathematical considerations. The alignment chart is not claimed as being an ideal method for the presentation of facts for analysis as it is of little use for that purpose, but it is suggested for quick calculation of data from complicated formulas and is seen as possessing manifest advantages over the more conventional methods.—*World Power,* April, 1928.

*Study of the Operation of the Multivibrator.*—Yasukazu Namba and Shogo Namba.—The multivibrator used for the purposes of frequency standardization and incorporating the valve-maintained tuning fork is considered by the authors. This discussion illustrates the experimental results obtained in the study of frequency and wave forms and discusses the findings with respect to both the analytical theory and experiments. The results of the experimental and analytical determination check very closely and are completely illustrated.—*No. 218, Researches of the Electrotechnical Laboratory (Japan).*

### *Motors and Control*

*Clutch Pulley for Induction Motors.*—J. Bethenod.—To diminish the starting current of an induction motor with short-circuited armature various types of clutch pulleys have been introduced in late years, most of them based upon a centrifugal operating principle. The pulley described in this article, contrary to former designs, is exceedingly simple, having no springs or internal bearings. The construction consists of an inner pulley, keyed to the motor shaft, and a concentric outer pulley, loosely turning around the former. Between these two are arranged twenty identical punched U-shaped metal pieces, which can rock over ribs cast into the two pulleys. When the motor assumes speed, these pieces begin to press against the inner periphery of the pulleys, causing such an amount of friction as to take the outer pulley along gradually. Holes are provided in the sides to admit a current of cooling air.—*Revue Générale de l'Electricité,* March 24, 1928.

*Electrical Drives in Rubber Factories.*—The power requirements and motor specifications in connection with the various processes in rubber manufacture have been outlined in relation to several specific installations. Safety devices, including a free-fall safety brake and similar items of protective equipment, are considered. The most important feature of this safety brake lies in the fact that the weight falls absolutely freely until impact occurs between the brakeshoe and the brake disks. As soon as the brakeshoe is applied the weight is released through special mechanism in such a way that the energy stored up in it is applied without shock to the brakeshoe. Consequently, the rapid application of the braking force insures that the required bodies are brought to rest in the shortest time and without vibration.—*Brown Boveri Review (Switzerland),* April 1928.

### *Heat Applications and Material Handling*

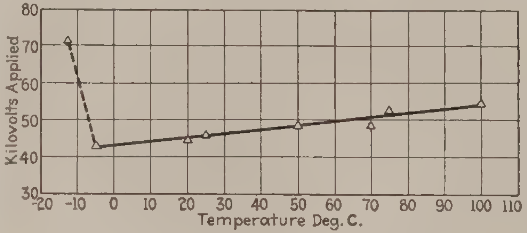
*Annealing of Non-ferrous Metals in the Electric Furnace.*—Robert M. Keeney.—Selection of the source of heat for the annealing of non-ferrous metals and alloys is an economic problem, according to the author, and the decision should be based on the overall cost of the finished product with the different forms of heat. For annealing in finished stages electric furnaces are said to have proved more economical than oil or gas, in many cases resulting in an annual return of 50 per cent on the investment. In the rolling mill, however, little progress has been made, although the cost of electric annealing, on a heat basis only, compares favorably with the cost of oil annealing. This situation is due to failure to consider economies in over-all cost which electric annealing may produce, the basis on which electric heating has made such great progress for tonnage production in the motor industry.—*Report American Electrochemical Society,* April, 1928.

*Condensers for Welding Machines.*—I. C. Fritz.—Various attempts have been made in the past to overcome the very low power factor of arc-welding and resistance-welding machines. Arc-welding sets with an induction motor and direct-current generator operate usually with 0.4 to 0.8 power factor and an efficiency of 50 per cent, while single-phase arc-welding transformers produce as low as 0.1 power factor load. It is suggested here that by connecting a small condenser across the primary of the welding transformer the power factor can be restored to unity. If a compensation to 0.8 is satisfactory the condenser will be found to weigh about one-half of the transformer weight, to require about three-quarters of its space, and its cost is one-third that of the transformer. A welding outfit for 14 kva., requiring previously special connection to a power line, can be connected to the light supply when equipped with a compensating condenser, since it will call for only 4 kva. actual power consumption. — *Elektrotechnische Zeitschrift,* March 8, 1928.

## *Electrophysics, Electrochemistry and Batteries*

*The Effect of Curved Boundaries on the Distribution of Electrical Stress Around Conductors.*—J. D. Cockcroft.—An investigation, by the method of conformal transformation, of the distribution of electrical stress around certain systems of conductors which are important in high-tension practice. The effect of rounding the edges of the conductors in reducing the high stresses at the edges has been determined quantitatively and particular attention has been devoted to this phase of the subject. The methods used are applied to calculate the variation of the breakdown voltage with spacing distance between the electrodes. The two-thirds power law is derived as a limiting case for some of the electrodes and the effect of variation of electrode shape and of physical assumptions is shown. The theoretical results are compared with such experimental data as are available. Approximate formulas are derived, for the capacity of coaxial rectangular cylinders, which are an extension of the well-known correction for the corner of a Leyden jar, and their application to heat-conduction problems is pointed out. The results are reduced to graphical form.—*Journal of the Institution of Electrical Engineers (England),* April, 1928.

*Liquids as Insulators.* — Frank M. Clark. — A general consideration of liquid dielectrics has been undertaken by the author. These are said to bear a strong resemblance to gaseous dielectrics whose characteristics were described in a previous article in the same publication. The chemical, physical and electrical properties of the ideal liquid dielectric are outlined, as are those of the materials at present available. Temperature effects are considered to offer a major factor in the alteration of the properties of such insulating media and the author has included a consideration of the influence of catalysts upon the oxidation process as well as a review of the methods for detection and measurement of oil sludging characteristics. Other properties are likewise reviewed in considerable detail in connection with the test results and investigating procedure. — *General Electric Review,* April, 1928.



*Dielectric strength of mineral oil varies with temperature*

*Effect of Temperature and Other Factors on the Performance of Storage Batteries.* — G. W. Vinal and C. L. Snyder.—Experiments are described in this paper in which the effect of extreme conditions, such as low temperatures and high discharge rates, are determined separately for positive and negative plates of a lead storage battery. It was found that the temperature effects are less for the higher concentrations of the electrolyte in the case of positives, whereas the reverse is true for the negatives. Under extreme conditions, such as in airplane service, the negative plates are likely to become the limiting factor in determining the capacity. The best concentration of electrolyte for use in batteries under extreme conditions is a compromise between the requirements of the positive and negative plates. The change in capacity with temperature, when the capacity is limited by the positives, is inversely proportional to the changes in viscosity of the solution. The conditions under which localized freezing is liable to occur are indicated. The possible effect of these various factors upon the operation of airplane batteries is another phase of the subject which is discussed. — *Report American Electrochemical Society,* April, 1928.

## *Telegraphy, Telephony, Radio and Signals*

*The Principles of Relay Timing in Connection with Automatic Telephone Circuits.*—T. H. Turney.—The author has developed the theoretical considerations involved in the relay timing of automatic telephone circuits. The relay is first considered as a simple coil which leads logically to Helmholtz's law. The inclusion of a slug, ignoring flux leakage, increases the time constant of the relay. As the rise of flux no longer obeys Helmholtz's law when flux leakage is present a rough treatment giving two exponential terms is utilized in place of one. In order to examine the effect of flux leakage a little more thoroughly the relay core has been viewed as a transmission line. The slug becomes distributed inductance, and the resulting telegraph equations have been solved by Heaviside's expansion theorem. In no case is the actual motion of the armature considered in this paper. —*Journal of the Institution of Electrical Engineers (England),* April, 1928.

## *Miscellaneous*

*A Method of Analyzing the Performance Curves of Centrifugal Pumps.* —Joseph Lichtenstein.—Development of analytical and graphical methods for determining correction factors from test curves for use in bringing theoretical pump equations into harmony with practice are given in this discussion. It is stated by the author that centrifugal pump practice still bases its calculations on the one-dimensional theory which assumes a frictionless fluid flowing through an impeller with an infinite number of blades. It is evident, according to the author, that the results of this theory cannot well conform with actual practice where the number of blades is small and where friction and a turbulent flow of water are encountered. Attempts to introduce a theory better adapted to the actual pump design have been made. These theories are not utilized by the pump designer because they are more complicated and not so general as the classical theory, being based on certain profiles which would limit the engineer in his designs, but especially because they are also based on a frictionless non-turbulent flow, a supposition far from reality. The present discussion is therefore based upon empirical factors rather than upon theoretical ones. Certain assumptions have been made upon which the various factors are developed. The discrepancy between the theoretical results and the classical one-dimensional theory used in calculating centrifugal pumps and the actual practices introduces correction factors that can only be deduced from tests. Correction factors have been introduced in the equations of the classical one-dimensional theory and new equations have been developed which can be used for calculating new pumps.—*Transactions American Society of Mechanical Engineers,* January-April, 1928.

# News of the Industry

## Maryland Commission Again Refuses to Sanction Sale

The Maryland Public Service Commission on April 26 dismissed for the second time the application of the Electric Public Utilities Company of Chicago for permission to purchase for $518,000 the Home Electric Light Company of Lonaconing, the Emmitsburg Electric Company, the Antietam Electric Light & Power Company and the Midland Electric Light Company, all in western Maryland. During the rehearing the commission was informed by its engineers that the reproduction costs of the properties of the utilities would be approximately $315,000, less depreciation.

No detailed criticism of the proposed transaction was given out last week by the commission, which simply said that it "would be detrimental to the public interest." Last year when it disapproved the transaction the commission gave as its reason that it could not "see wherein the public will be benefited in the slightest degree." An appeal was taken to the Circuit Court of Baltimore, which upheld the commission. Then the case was taken to the Court of Appeals, which found this negative reason insufficient and sent the case back to the commission (Electrical World, March 10, page 528).

Considerable interest has been aroused in public utility circles and among state commissioners by this case because of its bearing on the proper commission attitude toward the proposed acquisition of independent properties at inflated prices.

## International Rules for Tests of Hydraulic Machinery

At the instance of the World Power Conference the International Electrotechnical Commission undertook at its meeting in Bellagio last year to elaborate suggestions for an international agreement regarding the regulations to govern water-power plants. The rules agreed upon in sectional conference were referred to the national committees of Germany and Sweden, to which had been granted the right to appeal before Jan. 31, after which the rules were to be proposed as international regulations.

A German hydraulics committee was formed, with the permission of the German National Committee, to study these questions, and this committee has recommended acceptance of the Bellagio agreement as containing general rules in outline, inside of which each country would be free to compile its own rules according to the local requirements. The committee is now revising the German rules, which may then serve as a basis for additional international agreements.

Above all, the question of the measurement of water volume is receiving undivided attention, and all available experience and comparative results, as well as tests now being made in German and foreign hydraulic laboratories, will be turned to account. The book of rules is to be supplemented by an appendix containing the principal terms in several languages, and formulas and values will be published in both the metric and English systems of weights and measures.

## Federal Trade Commission Digs Diligently

### Unearths Payments by Joint Committee to Former Governors of New Mexico and Nevada, but Bulk of Testimony Adduced Lacks Interest

Open sessions of the investigation of public utility companies ordered by the Senate continue to be held in Washington by the Federal Trade Commission and to elicit testimony varying from details of the purest routine to making public financial transactions which have been seized upon as ammunition by the newspapers and politicians eager to score points against the industry.

The most fruitful of the latter, from the point of view of opponents of privately owned utilities, was brought to light on Wednesday of last week, when a total of $5,299 was shown to have been paid to the law firm of Meechem & Vellacott of Albuquerque, N. M. This amount, according to Ira L. Grimshaw, assistant director of the Joint Committee of National Utility Associations, was for the firm's services in reporting the conferences of Western governors called in 1927 to endeavor to settle state disputes over Colorado River development. Judge Healy, the Federal Trade Commission's counsel, pointed out that Mr. Meechem, formerly Governor of New Mexico, had been appointed by Governor Dillon of that state to represent it at the conference. Mr. Grimshaw implied ignorance on his own part of that fact, and Mr. Meechem subsequently said to newspaper men in the West that there had been no desire or attempt to conceal his employment by the joint committee.

On the following day Judge Stephen B. Davis, director of the joint committee, was asked about $600 paid to former Governor James G. Scrugham of Nevada for expenses of two trips East. Judge Davis said these trips were financed at Mr. Scrugham's own suggestion and that the latter was working with the committee to reconcile diverse opinion on the Colorado problem. Mr. Scrugham was a member of Secretary of the Interior Work's fact-finding commission on Boulder Dam.

Distribution of Literature

Since its organization in June, 1927, the joint committee, testimony showed, had distributed nearly two million pieces of publicity and had paid $55,000 for salaries, $30,000 for booklets and other literature, $31,000 for special publicity services and $37,000 for its Washington office. No expenditures had been made to public men for articles or for the use of their name except the $7,500 paid, as reported last week, to Richard W. Child, former Ambassador to Italy, for his work on a Boulder Dam booklet edited by Frank Bohn. No money had been paid directly or indirectly to schools.

Edward S. Mansfield, in charge of educational activities in New England for the National Electric Light Association, told of a survey on co-operation between utilities and educational institutions being made under N.E.L.A. auspices by Dean C. O. Ruggles of Ohio State University.

Josiah T. Newcomb, counsel for the joint committee, testified that he did not feel the committee had been organized to oppose government ownership, though the members were against it. He agreed that the committee's principal function and his own were to represent the utility companies in all matters of pending legislation before Congress. He referred to an interview in which Senator Walsh of Montana was represented as saying that the utilities and their controllers had "taken two billion dollars from the circumambient atmosphere" and had issued securities with no assets behind them. The committee desired to dissipate such misinformation. Mr. Newcomb admitted the interest taken by his committee in tax revision, federal regulation of interstate transmission of energy, government operation of the Muscle Shoals plants, flood-control legislation, the Boulder Dam project and similar matters of legislation.

N.E.L.A. Witnesses

Paul S. Clapp, managing director of the N.E.L.A., and George F. Oxley, in charge of publicity, appeared before the commission on Friday and explained the advertising and other policies of the association. Mr. Clapp declared himself opposed to political propaganda.

When the commission resumed its

hearings on Wednesday, May 2, Clarence G. Willard of New Haven, secretary of the Connecticut Committee on Public Service Information, and A. Bliss McCrum, secretary of the Public Utilities Association of West Virginia, were examined and told about their activities. Mr. Willard testified that he was co-author of the "Connecticut Public Utilities Catechism," used in seventy high schools of his state. Mr. McCrum had taken part in opposition to the Boulder Canyon bill, acting, he said, at the behest of Mr. Oxley.

Other officials of public utility associations summoned to appear include Walter H. Johnson, Walter E. Long and A. G. McKenzie of Philadelphia and A. B. Millar of Harrisburg, representing electrical associations, bureaus or committees in Pennsylvania. A. B. Tunis and A. H. Herrmann of the Public Utilities Association of Virginia were summoned last week, but their testimony contained nothing of moment.

Senator Walsh took occasion last Friday to deplore from his seat a lack of public attention to the investigation and said that to insure greater publicity for the testimony elicited he would from time to time address the Senate on points revealed. Thus he will get extracts from the evidence into the *Congressional Record.*

# Boulder Dam Debate Waxes Warm

## Senator Ashurst of Arizona, Leading Opposition, Denounces Stand of California as Selfish—Chances of the Bill's Passage Thought to Diminish

By Paul Wooton

Washington Correspondent of Electrical World

When the debate on the Boulder Canyon Dam bill began in the Senate last week some of its opponents were willing to concede that the bill would pass that chamber. After a week of debate, however, the chances of the bill to get through the Senate have diminished. In the meantime no progress has been made with the measure on the House side. The rules committee has had several hearings, but as yet has given no intimation as to its intention to give this legislation a preferred status.

Unquestionably the most effective point which is being made against the bill in the Senate debate is that the government cannot afford to embark upon an experiment with the highest dam ever built with insufficient engineering data. In view of the St. Francis Dam disaster it is being argued that the United States must be one hundred per cent sure before undertaking this project. The fact that Senator Smoot, the chairman of the finance committee, with all the prestige which goes with that position, is so vigorous in his opposition has had no little influence in building up sentiment against the legislation.

A determined filibuster against the bill, led by Senators Ashurst and Hayden of Arizona, is being aided by the legislative situation. The tax bill is certain to displace the Boulder Dam measure for a week or more. The conference report on the farm relief bill will take time and other appropriation bills have to be considered. In addition, various other important measures are on the calendar for which consideration is demanded, and if the President vetoes the flood prevention bill, that question will again be precipitated into the debating arena.

Senator Johnson of California, who is leading the fight for the bill, has contented himself with very limited remarks, mostly confined to explanations of the bill's provisions. He urged the passage of the measure as the duty of Congress to rescue sixty-five thousand Americans in the Imperial Valley from the threat of flood and to solve the international problem which exists on the lower reaches of the river.

### Ashurst Versus Johnson

Senator Ashurst, who is leading the opposition, and between whom and Senator Johnson a heated exchange of words took place, takes strong exception to the constant references by the bill's supporters to the "power trust." He pointed out that all but one of the senators who are supporting the Johnson bill voted against the Walsh resolution. He declared that the Boulder Canyon Dam would offer no flood protection for the Imperial Valley within the lifetime of any one now occupying a seat in the Senate. He urged that Congress pass the bill providing for the protection of the Imperial Valley against flood and take up as a separate matter a decision as to whether or not Los Angeles should have potable water at the expense of the government and whether or not Los Angeles and other cities on the coast should have electrical energy at the expense of the government. He charged that the California senators fear that a flood-control dam might destroy their hope of obtaining water and electricity for their state at government expense.

In the course of the debate Senator Johnson expressed the opinion that Senator Ashurst had not offered his flood-control amendment in good faith. In reply Senator Ashurst said the project would have a better chance for approval when California statesmen speak with the voice of reason, instead of with the voice of selfishness and a "display of a forked tongue." He concluded those particular remarks by declaring that the present bill fails to square with the idea of fair play that even bullies and prize fighters hold.

### Wants Sixteen-Hour Debate

Urging that the Boulder Dam bill be considered on its own merits irrespective of appeals to prejudice concerning the alleged interests of power companies in the contest, Representative Douglas of Arizona on May 2 asked the House rules committee, if it should give time for the consideration of the bill, to allow the opposition to the measure abundant opportunity to develop its case on the floor. "If you see fit to bring this bill before the House," he said, "sixteen hours of general debate will be necessary to inform the members of vital issues at stake concerning the interests of the people of seven states and an expenditure of $300,000,000."

Mr. Douglas put forward as his chief objection to the bill the incongruity of undertaking an enormous and expensive power development to provide against floods in a region where there is no pressing flood menace. He also took issue with the statement that Los Angeles needs an additional water supply, substantiating his point with a quotation from a California state engineer to the effect that the city at present has enough water for fifty years. In answer to statements that there is a great need for more power in southern California, Mr. Douglas pointed out that both the city of Los Angeles and the Southern California Edison Company reduced their rates in 1927 in order to stimulate demand.

In conclusion Mr. Douglas sounded the warning that the whole policy of the government is at stake in the issue. "If the government is to go into the power business at Boulder Canyon," he said, "the field will be opened to put it into any competitive line of business." He also declared that the government could construct a steam power plant at Los Angeles, if its object is power development, and save expense.

Despite requests of representatives from other Colorado Basin states that time be given them to make statements, Chairman Snell of the rules committee announced that he had given the subject all the time that he could and that the committee would now devote itself to the consideration of the rule.

# Senator Smoot Takes a Hand in Boulder Dam Debate

An amendment in the form of a substitute for the Boulder Dam bill by which the problem of developing the Colorado River would be referred to a board of engineers which would make recommendations for flood-control measures was offered on May 1 by Senator Smoot of Utah. The Senator made the proposal at the close of a long speech begun on April 30, in which he criticised in detail the proposed engineering plans for the development of the Colorado River.

The Smoot substitute would make available an appropriation of $20,000,000 "for the purpose of carrying out the investigation and building the flood-control structures." If a storage dam is the type of flood-control structure decided on, Senator Smoot's proposal provides that the seven-state Colorado River compact shall be consummated before the dam is begun, or "if the present incomplete Colorado River compact proves too difficult of ratification, an easier compact, not involving the troublesome question of title to water rights, may be substituted."

Senator Smoot, who is chairman of the finance committee, also announced that he would call up the tax bill on May 3, after which he would seek to keep it continuously before the Senate until it is disposed of. This action will displace the Swing-Johnson bill on the calendar, at least temporarily.

## Representative Berger "Goes the Whole Hog"

A national "superpower system" is provided in a bill introduced in the House on Monday by Representative Berger of Milwaukee, a Socialist. Declaring that the so-called "superpower lobby" represents "the most corrupting influence in the United States today," Mr. Berger said his measure is designed to bring about conservation of the nation's natural resources, the co-ordination of irrigation, flood control, navigation and hydro-electric power production, the enlargement and expansion of the Reclamation Service in the field of agriculture, and federal aid to states, cities, counties, districts and other political subdivisions in the development of superpower systems, with service at cost.

## P. G. & E.'s New Mokelumne River Project

The Pacific Gas & Electric Company has filed with the Federal Power Commission an application for the further water and power development on the upper Mokelumne River, 50 miles northeast of Jackson, which has previously been described in the ELECTRICAL WORLD. The company proposes to erect a rock-filled dam, with a concrete face, approximately 300 ft. in height, 800 ft. thick at the base and 25 ft. wide at the top. The crest will be 1,300 ft. long and the storage capacity 130,000 acre-feet.

The application further calls for the erection of the Salt Springs power house at the base of the dam, which will have an installed capacity of 11,000 hp.; the construction of a concrete-lined canal and tunnels for the conveying of water from Salt Springs to a proposed regulating reservoir on Tiger Creek; the construction of a forebay on Tiger Creek from which water will be dropped approximately 1,200 ft. through penstocks to the proposed Tiger Creek power house, which will have an installed capacity of 67,000 hp., and the erection of a 110,000-volt power line from the Salt Springs power house to the Tiger Creek power house.

## N.E.L.A. in Joint Conference on Shift of Industry

A joint conference of the policy holders' service bureau of the Metropolitan Life Insurance Company and the civic development committee of the N.E.L.A. was held in the Metropolitan Life Building in New York City on Thursday. The purpose of the conference was to discuss a survey of what industries are moving, where and why, and the relative advantages of small and large cities as manufacturing sites, and to consider ways in which the personnel of the two organizations can co-operate in collecting fundamental industrial economic figures. Preston S. Arkwright, president of the Georgia Power Company, is chairman of the N.E.L.A. civic development committee, containing thirteen prominent executives.

## Projected Water Power in the Ozarks, 245,000 Hp.

RECENT granting by the Federal Power Commission of a preliminary permit to the White River Power Company for a long-mooted hydro-electric project in the Ozarks at the Missouri-Arkansas border has revived hopes of extensive new water-power development in that region. The permit embraces a 226-ft. dam near Cotter, Ark., with backwater to the Empire District Electric Company's Ozark dam at Powersite, Mo.; two high reservoir and power dams on the North Fork and Buffalo Fork and a series of low-head power dams between Cotter and Wall's Ferry. The aggregate immediate installation of the White River Power Company's project is placed at 165,000 hp. or more, and it is maintained that double this amount of power can be generated when required. The Empire District Electric Company on its part is sponsor for an 80,000-hp. project at Table Rock, in Stone County, Mo., further along the river, where a dispute with county authorities is delaying action.

## Electrochemists at Bridgeport Discuss Batteries

The chemical production of electricity was the major topic of the American Electrochemical Society at the spring meeting held at Bridgeport, Conn., on April 26 to 28. More than two hundred members were in attendance.

Two sessions on Thursday dealt with primary cells. The modern dry cell was discussed in several papers with especial reference to life tests and depolarizers. One notable paper by Bruce K. Brown dealt with the use of graphitic oxide instead of manganese dioxide as a dry-cell depolarizer. The graphitic oxide gives a cell of lower voltage and is more expensive at the present stage of development but has promising possibilities. Marion Eppley gave two research papers on requirements in the production of standard cells. M. L. Martus discussed the caustic-soda battery and told about its characteristics. For the first time the technical details of the aluminum electrolytic rectifier were published in a paper by W. E. Holland, and a companion paper by H. O. Siegmund discussed the aluminum electrolytic condenser. Other papers dealt with storage batteries and storage-battery testing.

On Thursday night two excellent lectures were given. Dr. S. C. Lind, retiring president of the A.E.S., gave a lecture on the theory of chemical action in electric discharges in gases. He precipitated oils and solids from hydrocarbon gases by means of radium emanations and duplicated these tests with electric discharges. The second lecture was by Dr. Bergen Davis and dealt with the refraction of X-rays. These rays were observed by a double refracting spectroscope and their angle of refraction was measured.

Electrothermic applications of electricity were discussed on Friday. Robert M. Keeney, illustrating his paper with a film, described the growth of electric heat in industry and cited details of development in Connecticut. R. H. Leach gave operating data on the induction furnace for melting silver. C. M. Hoff told of the production of nitric and hydrochloric acid by use of electrodes immersed in the impure acids. By this means the resistance paths became heated and the boiling which resulted permitted distillation of pure acids. He said the new process replaced eight men with one and reduced production costs very greatly.

On Saturday the session was devoted to electrodeposition. Especial attention was given to chromium plating, and a noteworthy paper on this topic was presented by L. E. Grant and L. F. Grant. Chromium plating is looked upon favorably in industry, but to get good commercial results precision control and knowledge are required.

Visits were made to manufacturing plants in Bridgeport, Waterbury and New Haven. Paul J. Kruesi, president of the American Lava Company and other electrochemical concerns in Chattanooga, Tenn., was elected president. The fall meeting will be in Charleston, W. Va., on Sept. 20, 21 and 22.

## A.E.S.C. Changes Its Procedure

*Flexibility Made Main Element in Rules Adopted to Speed National Standardization—Steps in Development and Approval Are Listed*

EXTENSIVE revision of its rules of procedure to speed industrial standardization work on a national basis is announced by the American Engineering Standards Committee. The chief object in broadening the procedure has been to make it so flexible that it may easily fit all of the varied conditions to be met in the wide range of industrial subjects covered by the committee's work. The revision is based upon the experience of the committee during its nine years of activity as a national standardizing body.

Three important changes are made in the procedure. Heretofore each sectional committee—essentially a joint committee composed of representatives of the various groups interested in the particular work in hand—has acted under the administrative support and direction of one or more of the interested bodies, which have been termed sponsors. A sectional committee may now operate autonomously, reporting directly to the A.E.S.C., or it may act under sponsors as before. The second change recognizes "proprietary" standards and makes possible the revision of such standards within a single organization on condition that it be shown that a standard is acceptable to the groups concerned. This method is particularly applicable to highly specialized fields in which the standard of an organization has already achieved a position of recognized eminence. The third change provides for very simple cases. The approval of standards under such cases is based upon the action of a conference followed by written acceptances of the interested groups.

The revised procedure states that the different methods are founded on the principle that the basic test to be applied in all cases is the fact of the assent, affirmatively expressed, of the groups having substantial interest in the standard. Such groups have an inherent right to representation on the body dealing with the subject matter of the standard, but it is not essential that this right be exercised.

The steps in the development on revision of a standard by a sectional committee will be:

1. Standardization proposed by responsible body.
2. General conference called by the A.E.S.C. to consider proposal and to decide whether the work shall be done; if so, whether the sectional committee shall operate under a sponsor or autonomously.
3. Recommendation of conference acted upon by A.E.S.C.
4. Organization of a sectional committee.
5. The make-up and personnel of sectional committee approved by the A.E.S.C.
6. Standard drafted by sectional committee.
7. The draft standard published or circulated for criticism.
8. Proposed standard approved by sectional committee by letter ballot.
9. Proposed standard approved by sponsor, if there be a sponsor, or formally indorsed by at least one co-operating body if the sectional committee is autonomous.
10. Standard approved by the A.E.S.C.
11. Standard published by sponsor or by the A.E.S.C. if sectional committee is autonomous.

The steps in approval of existing or proprietary standards will be:

1. An existing or a proprietary standard submitted to the A.E.S.C. for approval by a responsible body.
2. Investigation of facts regarding consensus through A.E.S.C. agencies, or the development of the acceptability of the standard through a representational committee.
3. Standard approved by the A.E.S.C.
4. Standard published.

The steps in the development of a standard by general acceptance will be:

1. Standardization proposed by a responsible body.
2. Survey of field made and draft standard produced by working committee.
3. Draft standard considered by general conference.
4. Proposed standard formally accepted by groups concerned.
5. Standard approved by the A.E.S.C.
6. Standard published.

The governing authority of the American Engineering Standards Committee is at present vested in 63 men, representing 36 national organizations, industrial, technical and governmental. About 350 national organizations are officially co-operating in the work, with 2,100 individuals engaged on various committees. Up to the present time 111 national standards have been approved, and 164 additional projects representing almost all branches of industry are under way.

## "Teach Children to Respect Utilities"

### Before State Association Governor Baker of Missouri Advocates Public Instruction Concerning Them—Glowing Predictions Made About Farm Service

FOUR hundred representatives of Missouri utility companies attended the three-day convention of the Missouri Association of Public Utilities at Jefferson City on Thursday to Saturday of last week. The address of welcome, delivered by Governor Sam A. Baker, went further than to express the customary amenities. The Governor strongly advocated the study in the public schools of the state of public utilities and the service they render. "I believe the public school curriculum should be so modified as to have a place for public utilities," he said. "Teach the children from the time they know anything to respect public utilities and to have some knowledge of them. There are still some of our greatest educational institutions that never undertake to teach anything about public utilities. We have the school of journalism, we have the school of engineering, we have the school of pharmacy, we have the medical school, and we should, right along with these activities, teach the benefits of public utilities."

A miniature electrified farm was an exhibit of the convention as the joint contribution of the agricultural colleges and the power and light companies of Missouri, Iowa, Kansas and Nebraska. R. R. Parks of the Missouri Agricultural College, Columbia, had charge of the farm. President W. H. Henby in his address predicted that eighty thousand Missouri farms will be electrified by 1948 and that the total cost of this development to the farmers and utilities will be about $200,000,000. He declared that the electrification of farms is the biggest task before the utilities, that rapid progress is being made and that the job will be done. He said that about five thousand Missouri farms are now using electricity.

"There is a vast field open to the utilities in assisting the chambers of commerce and other civic organizations in industrial development of the communities in which they operate," F. S. Dewey, vice-president of the Kansas City Power & Light Company, declared. He pointed out that the kilowatt-hours of electricity and cubic feet of gas produced by the utilities form a good measuring rule in determining the industrial development of any given territory.

Earle W. Hodges, director of public relations for Henry L. Doherty & Company, said that whether a public utility was a "good citizen" depended very largely upon its employees. Missouri utilities, he said, are following the proper trend by instilling into their workers civic and state pride. He advocated newspaper advertising to keep the utilities in close touch with the public.

L. A. Petit, Jr., operating vice-president of the Missouri Power & Light Company, Kansas City, Mo., in an address on Friday pictured electricity as an economic and social equalizer and declared that the liberal use of electric power in industry has done more to improve the standard of living and to increase per capita wealth in America than any other single thing. It has also, he said, increased the productivity of labor, thus making possible higher wages and a shorter work day. It would make decentralization of industry possible and raise agriculture to the same plane of prosperity that industry has occupied.

L. A. S. Wood, manager of the street-lighting section of the Westinghouse Electric & Manufacturing Company, South Bend, Ind., spoke on "The Public Utility Company's Responsibility in Relation to Street Lighting," and W. L. Berry, assistant sales manager of the Union Electric Light & Power Company, spoke on "Load Building."

Thomas J. Brown, chairman of the Missouri Public Service Commission, was the only speaker at the annual banquet, held at the Missouri Hotel on Friday night. The trend of his remarks was that the public utility is as much an agent and servant of the public as are members of the commission and he urged a better understanding of the meaning of state regulation and the workings of the commission, whose duty it is to see that good service is furnished and that the company in return has just and adequate rates. "Regulation means to a great extent the elimination of competition" he continued. "When I became a member of the state commission I was firmly convinced that competition should not be eliminated. I am now entirely 'sold' on the idea of state regulation."

A feature of the final session on Saturday morning was a technical paper on the steam-heating business prepared jointly by W. C. Kaber, engineer of the steam-heating department of the Union Electric Light & Power Company of St. Louis, and T. S. Ayers, superintendent for the same company.

New officers were elected as follows: President, A. E. Reynolds, Springfield Gas & Electric Company; first vice-president, T. J. Stricker, Kansas City; second vice-president, E. D. V. Dickey, Hannibal; third vice-president, Samuel W. Greenland, St. Louis; secretary and treasurer (re-elected), F. D. Beardslee, St. Louis.

## Progress in Electric Welding Reviewed by Society

Continued progress in the art of fusion welding by electric and gas processes was made evident by papers, discussions and committee reports at the annual spring meeting of the American Welding Society, held at the Engineering Societies Building, New York, April 25, 26 and 27. This progress, it was shown, is mainly in the perfecting of technique, the establishment of preliminary standards for qualifying welders and supervising their work and the advancement of the test programs for welded pressure vessels and steel structures.

At a meeting of the pressure-vessel committee it was pointed out that the support of tank manufacturers and manufacturers of electric welding equipment is needed to insure an early start on an extensive test program to be carried on jointly by the American Welding Society and the American Society of Mechanical Engineers. These tests will supply essential data sought by the A.S.M.E. boiler code committee as a basis for proposed modifications in the code for unfired pressure vessels.

The meeting of the structural steel welding committee brought out the fact that funds for a similar structural research program are fully subscribed, assuring the completion of tests to establish unit stresses and other data.

A preliminary progress report on qualifications of welders, inspection and supervision was presented by H. H. Moss and A. M. Candy. This covered the fields of structural steel and industrial piping and was followed by prepared discussions covering structural steel, piping and pressure vessels.

The meeting closed with a session on the welding of the new Ford car, in which all processes are used, and a meeting of the American Bureau of Welding, at which the progress made by various research committees of the society was reviewed.

Officers elected for the ensuing year are: President, F. T. Llewellyn; senior vice-president, A. E. Gaynor; divisional vice-presidents, Ernest Lunn, J. W. Meadowcroft and H. P. Peabody.

## Purchases and Mergers

*Ashtabula, Ohio, Votes to Sell Municipal Plant if $2,225,000 or More Can Be Realized—$2,000,000 Cash Offered for Freeport (N. Y.) Municipal Plant*

VOTERS of Ashtabula on April 24 approved a proposal to sell the municipal light and power plant for not less than $2,225,000. The issue carried by a majority of 1,036 votes. Last November a similar proposal was defeated by 32 votes. The voters last week also authorized the Cleveland Electric Illuminating Company to extend its lines inside the city limits of Ashtabula to serve the docks and railroads. Ashtabula, which has a population of 25,000, is the largest city in Ohio depending for electric service entirely on a municipal plant. The Public Ownership League of America devoted eleven pages of *Public Ownership*, its monthly journal, edited by Carl D. Thompson, to arguments against authorizing the sale.

The Long Island Lighting Company has made a formal offer to the Village Trustees of Freeport, N. Y., to buy the municipal light and power system for $2,000,000 cash. The sum would, it is said, wipe out Freeport's bonded indebtedness and leave a margin. It is expected that public opinion on the matter will be indicated at a proposed forthcoming referendum on the question of floating a bond issue of $250,000 for the purchase of equipment for the municipal plant. The Long Island Lighting Company's offer will hold good until Nov. 1.

Acquisition by the American & Foreign Power Company of the Mexican Utilities Company is announced. The Mexican Utilities Company was organized in 1925 and controls the Guanajuato Power & Electric Company and the Central Mexico Light & Power Company. Irving W. Bonbright is chairman of the board.

The proposed merger of the Washington (D. C.) traction companies, now before Congress, has attracted criticism at the hearings of the District committee of the House, where William A. Roberts of the Federation of Citizens' Associations declared that control of the Washington Railway & Electric Company and the Potomac Electric Power Company reaches back to the North American Company. He expressed the opinion that the La Follette anti-merger act makes unlawful the indirect control which, under the proposed plan, the North American might have over the local power supply and the potential source at Great Falls in view of its holdings in the Washington Railway & Electric. The Senate committee is understood to be waiting on the House, and doubt is expressed whether final action will be taken this session.

The Central Hudson Gas & Electric Corporation has made application to the New York Public Service Commission for authority to acquire for $500,000 all of the outstanding capital stock and mortgage bonds of the Red Hook Light & Power Company and the outstanding stock of the Ducci Realty Corporation, which owns real estate and water rights in Bingham Falls, Columbia County, where the Red Hook hydro-electric company's plant is located. The Central Hudson Gas & Electric Company has also made application for authority to acquire the outstanding capital stock of the Millerton Electric Light Company, serving Millerton and the town of Northeast, in Dutchess County, and for approval of the merger of the Millerton company with the Central Hudson Gas & Electric. The Millerton company is now controlled by the Connecticut Power Company of New London. The price stated is $105,000 in cash and 2,000 shares of Central Hudson non-par-value common stock.

Sale of the Waverly (Ohio) municipal light plant to the Ohio Utilities Company took place recently.

The Ohio Electric Power Company of Oberlin has purchased from the New Bremen corporation the transmission and distribution line serving the village of Lock Two. New Bremen obtains its own energy from the company.

Purchase of the electric light system at Sharpsburg, Ky., by the Kentucky Electric Development Company, Louisville, is announced. This company has been in operation a little more than a year and now furnishes power for seven towns in Pendleton and Shelby Counties.

When the Stonewall Power Company sold out its entire interests last week to the Virginia Public Service Corporation of Charlottesville, for approximately $250,000, a fight for the right to supply electric light and power to Mannassas and Prince William County was brought to a conclusion. About a year ago the Virginia Public Service Corporation made the Town Council of Manassas an offer of between $80,000 and $90,000 for its franchise, power plant and lines. This offer was rejected by the Town Council. A few months later a corporation, with headquarters in New Jersey, known as Rivers & Streams, Incorporated, began the construction of a dam at Bland's Ford, on Occoquan Run, and acquired all lines and rights outside of Manassas, subsequently selling out to the Stonewall Power Company.

The municipal electric light, water and ice plants in Donalsonville, Ga., have been sold to the Georgia Power & Light Company, not to the Georgia Power Company, as erroneously reported last week.

Jonesboro (Ark.) citizens are at loggerheads over the proposed sale of the municipal water and light plant, a property owners' league advocating disposing of it for $1,200,000.

On April 1 the electric and gas properties of the Central Power & Light Company at Natchez, Miss., were transferred to the Southwestern Gas & Electric Company, an operating subsidiary of the Central & Southwest Utilities Company, because of the great distance separating Natchez from the remaining properties of the Central Power & Light Company and the proximity of Natchez to the properties of the Southwestern Gas & Electric. All are Insull companies.

James R. Darby, owner of the Weimar (Tex.) Power & Light Company, has sold the business to the Middle States Utilities Company, with headquarters at Chicago.

That company also has purchased the La Grange (Tex.) Light, Power & Water Company.

The Walterboro (S. C.) municipal electric plant has been bought by the South Carolina Power Company for $56,000.

Fifty thousand dollars has been offered for the Benson (Minn.) municipal electric plant by the Otter Tail Power Company. Engineers have informed the city that it would take $223,000 to modernize the plant.

An offer of about $57,500,000 by the Power Corporation of Canada, through A. J. Nesbitt of the Nesbitt, Thomson Company of Montreal, for the British Columbia Electric Railway Company brings the number of bids recently made for control of the latter property to four, of which the one just referred to is much the highest. The other three bids include a previous one from the Nesbitt interests, one from the Holt interests of Montreal and one from Lord Rothermere and his associates in England, where the company's stock is now held.

## Briefer News

New Transmission Line for Iowa.—A 47-mile high-tension line connecting the Northwestern Light & Power Company plant at Sibley, Iowa, with George, Boyden, Little Rock and Hull is being planned by the utilities company and will be started soon. The approximate cost is $100,000.

Possibilities of Chilco River Watershed in British Columbia.—The government of British Columbia will take steps this summer to determine definitely the water-power possibilities of the Chilco River country, midway between Vancouver and Prince George, over which a water-power reserve was placed a year ago. The water powers of that locality have been estimated to be capable of developing 1,000,000 hp., and the government will now send a survey party to make scientific measurements. This will probably take three years.

Mechanical Engineers' Pittsburgh Meeting.—"Some Economic Factors in Power-Station Design," by H. B. Brydon, and "High-Pressure Steam Boilers," by George A. Orrok, are the two papers scheduled for presentation on Thursday morning, May 17, at the central-station power session of the spring meeting of the American Society of Mechanical Engineers. This meeting will be held at the William Penn Hotel, Pittsburgh. On the preceding day there will be two papers dealing with engineering education—"Industrial Co-operation in Education," by A. T. Jewett, and "Education and Training as Applied to the Engineer," by F. L. Bishop.

Mountain States Power Moves Back to Albany, Ore.—Moving of the general offices of the Mountain States Power Company from Tacoma, Wash., to Albany, Ore., was effected early in April. The operating and treasury departments were moved to Tacoma from Albany about two years ago, at which time the engineering and electric new-business departments were kept at Albany so as to be near the center of the Willamette Valley Division. The principal officials returning to Albany in the present move are Vice-President C. M. Brewer, General Auditor W. L. Fitzpatrick, and John N. Adams, head of the publicity department.

Missouri Public Service Company to Have Headquarters at Warrensburg.—The Missouri Public Service Company will by June 1 establish its general headquarters at Warrensburg, Mo. The company now serves eighty towns in western Missouri.

New Plant at Yoakum, Tex., for Texas-Louisiana Power.—The Texas-Louisiana Power Company will construct a new electric power plant at Yoakum, Tex., at a cost of $150,000, it is stated. The company also plans to construct a system of power transmission lines in that part of the state, invading the field which is now occupied almost exclusively by the Central Power & Light Company.

Line Extensions in Oklahoma.—The Southwestern Light & Power Company has started construction on a 33,000-volt electric transmission line from Duncan to Addington and from Waurika to Ryan, guaranteeing uninterrupted service by a loop connected to the company's generating plant at Lawton and its standby plant at Waurika. The company is also constructing a 33,000-volt line from Clinton to Arapaho and a distribution system at Arapaho. The 22,000-volt line from Hammon to Cheyenne and Strong City is finished, as are also the distribution systems in Cheyenne and Strong City. Erection of the steel towers for the Red River crossing to connect with the transmission systems of the Southwestern Light & Power Company at Frederick and the West Texas Utilities Company at Vernon has been completed in recent weeks.

New Unit for Toronto (Ohio) Plant Nearly Ready.—The fourth unit of the Pennsylvania-Ohio Power & Light Company's plant at Toronto, Ohio, will soon go into operation, increasing the capacity of that station from about 112,500 kva. to 150,000 kva. The third unit was installed only last fall.

To Enlarge Chihuahua Hydro Plant.—Plans of the Mexico Northern Power Company for increasing the capacity of its hydro-electric plant in La Boquilla, State of Chihuahua, and construction of a large irrigation system have been approved by the Mexican government. The improvements will cost approximately $1,500,000 United States money, it is stated. This company is owned by Canadian interests. It constructed a large dam across the Conchos River about twenty years ago and installed a hydro-electric plant which, by means of transmission lines, furnishes power and light for Parral, Chihuahua, Santa Rosalia and a number of mining districts.

Northern New York Utilities to Develop 12,000 Hp. on Beaver River.—The Northern New York Utilities of Watertown, N. Y., will immediately start the development of water power at Mosher Falls on the Beaver River, where about 12,000 hp. will be developed, two units of 6,000 hp. each being installed. An additional development of 12,000 hp. may be made later. It is expected that the work will be finished this year. The Mosher Falls has a 216-ft. head. A concrete dam 100 ft.

## Floodlighting Embellishes the Original Capitol of Iowa

The dignified simplicity of Iowa's "Old Capitol" at Iowa City is especially well brought out at night by floodlighting. Four L-15 1,000-watt projectors are used to light up the tower; 12 L-1 500-watt projectors light the remainder of the building. The lighting installation was made by the General Electric Company. The old building has been termed the cradle of Iowa, as it was the first Capitol of the state. It is now the heart of the University of Iowa and houses all the administration departments of the university.

high and 1,000 ft. long is to be constructed, and 10,000 ft. of pipe line, 10 ft. in diameter, is to be laid to the surge tank, two miles away. About 320 acres of timber land will be flooded.

Rochester Gas & Electric Wants Additional Land on Genesee. — The Rochester Gas & Electric Corporation has filed with the New York Public Service Commission a petition requesting the commission to find, in accordance with the conservation law, that certain real property on the Genesee River in the city of Rochester is necessary to the improvement and full utilization of the company's water-power development in that city. Under the law the commission must make such a finding before the petitioner can institute condemnation proceedings. The commission will fix a date for a public hearing.

Plant to Be Built at Aberdeen, Wash., While Awaiting Cowlitz Power.—The Grays Harbor Railway & Light Company, Aberdeen, Wash., will build an extension to its central generating plant at Electric Park, to cost $1,500,000, W. W. Briggs, vice-president and general manager, announces. The new unit will develop 10,000 hp. and will more than double the capacity of the station. Mr. Briggs also announces that the construction of this unit will in no way interfere with the ultimate development of the Cowlitz power project, but that it is being built to provide for industrial expansion expected before the Cowlitz power becomes available five years hence.

Senate Passes Bill for Hydraulic Laboratory.—The United States Senate on April 13 passed the Ransdell bill authorizing the establishment of a national hydraulic laboratory in the Bureau of Standards. A similar bill was introduced by Senator Ransdell in 1922 by request of the American Engineering Council in an effort to carry out a recommendation made by John R. Freeman. The commerce committee on two previous occasions reported the bill favorably and urged its passage, but it took the flood of 1927 to muster the necessary support behind the bill to insure its success. The bill was supported strongly by Secretary Hoover. It authorizes an appropriation of $350,000.

Negotiation Under Way for Elephant Butte Power.—During the past year the El Paso Electric Company has been carrying on negotiations with the Water Users' Association looking toward construction of an 18,000-kw. power plant at Elephant Butte Dam in New Mexico and a transmission line to El Paso by the Water Users' Association and purchase of the power by the El Paso Electric Company. Elephant Butte Dam was constructed several years ago for irrigation purposes only, but engineers estimate that approximately 18,000 kw. of power will be available for a few months out of each year and it is this power that the electric utility would buy. An agreement has been worked out and is now under consideration by the Water Users. It will be necessary for them to secure approval of the Secretary of the Interior.

Nebraska's State Plant Is Started. —The new power plant built by the State of Nebraska at the state penitentiary, 5 miles south of Lincoln, at a cost of $150,000, has been put into service and will light all state institutions in and about the city, including the ten-million-dollar Capitol, now nearing completion. The state refused to contract for energy with the Iowa-Nebraska Light & Power Company. It claims that the new plant has a fuel-saving capacity of 50 per cent over the old equipment.

## Coming Meetings

**[A complete directory of electrical associations, with their secretaries, is published in the first issue of every volume. For latest list see Electrical World for Jan. 7, page 80.]**

American Institute of Electrical Engineers—New Haven regional meeting, May 9-11; national convention, Cosmopolitan Hotel, Denver, June 25-29. F. L. Hutchinson, 33 West 39th St., New York.

Middle West Division, N. E. L. A.—Hotel Statler, St. Louis, May 9-11. T. A. Browne, 1519 O St., Lincoln, Neb.

Arkansas Utilities Association—Arlington Hotel, Hot Springs National Park, May 14-16. R. I. Brown, Arkansas Power & Light Co., Little Rock.

American Society of Mechanical Engineers—Pittsburgh, May 14-17. Calvin W. Rice, 29 West 39th St., New York.

Indiana Electric Light Association (jointly with Indiana Public Utilities Association) — Columbia Club, Indianapolis, May 22-24. William Stokes, 1548 Consolidated Bldg., Indianapolis.

National Electric Light Association—Atlantic City, June 4-8. P. S. Clapp, 420 Lexington Ave., New York.

American Association of Engineers—Hotel Hussman, El Paso, Tex., June 4-6. M. E. McIver, 63 E. Adams St., Chicago.

Electrical Supply Jobbers' Association—The Homestead, Hot Springs, Va., June 5-8. E. Donald Tolles, 165 Broadway, New York.

National Electrical Manufacturers' Association—The Homestead, Hot Springs, Va., June 11-15. S. N. Clarkson, 420 Lexington Ave., New York.

Pacific Coast Division, N.E.L.A. — Hotel Huntington, Pasadena, Cal., June 12-15. S. H. Taylor, 447 Sutter St., San Francisco.

Georgia Electrical Association—Savannah, June 14 and 15. J. J. McDonough, Georgia Power Co., Dublin, Ga.

Northwest Division, N.E.L.A.—Portland, Ore., June 19-22. B. Snow, 1208 Spalding Bldg., Portland, Ore.

Canadian Electrical Association—SS. "Richelieu" from Montreal to Saguenay and return, June 20-23. H. M. Lyster, 712 Power Bldg., Montreal.

Association of Iron and Steel Electrical Engineers—Hotel Stevens, Chicago, June 25-28. J. F. Kelly, Empire Bldg., Pittsburgh.

American Society for Testing Materials — Chalfonte-Haddon Hall, Atlantic City, N. J., June 25-29. C. L. Warwick, 1315 Spruce Street, Philadelphia.

East Central Division, N.E.L.A.—Cedar Point, Ohio, July 10-13. D. L. Gaskill, Greenville, Ohio.

Chief Justice Wilson of Maine Named Master in Cambridge Case.—Chief Justice Scott Wilson of the Supreme Court of Maine has been appointed master to hear the case brought by the Cambridge Electric Light Company against the Massachusetts Department of Public Utilities in connection with the commission's order reducing its maximum residential and commercial lighting rate from 8 cents to 5.5 cents per kilowatt-hour.

Middle West N.E.L.A. Meets at St. Louis Next Week.—About four hundred delegates are expected to attend the annual convention of the Middle West Division of the National Electric Light Association, composed of electric light and power companies in Missouri, Iowa, Kansas and Nebraska, to be held in St. Louis on May 9, 10 and 11. The proposed method of Mississippi River flood control will be discussed by Major George R. Young. Judge C. W. Appleton, vice-president of the General Electric Company, will discuss "Government in Business." Public utility financing will be presented from a banker's viewpoint in an address by A. C. Allyn of Chicago. Prominent representatives of the parent body also will address the gathering.

Third Unit at Bartlett's Ferry, Ga., to Go in This Year. — Preliminary work on an extension to the Bartlett's Ferry hydro-electric station of the Columbus (Ga.) Electric & Power Company is finished, and unit No. 3 will be installed, it is announced, by Sept. 1. Like the two previous units, the new generator will be rated at 22,000 hp., thus increasing the plant's capacity to 66,000 hp. Ultimately a total of 110,000 hp. may be installed. New steel penstocks, control equipment and a transmission substation form part of the work to be done this summer. The new unit will consist of a General Electric generator and an Allis-Chalmers waterwheel. The two units already in service are of Westinghouse and S. Morgan Smith manufacture.

Device for "Shocking Away" Trespassing Fish.—J. E. Yates, electrical engineer for the Pacific Power & Light Company in Oregon, claims to have perfected a safety device by the use of which hydro-electric utilities may prevent the destruction of fish by turbine wheels. According to the State Fish Commission, Mr. Yates' invention is the first of the kind to be successfully used. It consists of two rows of parallel electrodes suspended from a wooden framework above the water. The rows are 4 ft. apart and the electrodes 3 ft. apart. The electrodes are at approximately the same level near the bed of the stream. An electric field set up about the electrodes will reach in equal strength from the surface of the water to the bottom of the stream. Its strength will taper off in proportion to the distance upstream and downstream from the center of the field. The device is so constructed that when a fish approaches a tailrace it will swim into the edge of the electric field and either be immediately turned back or, if it attempts to enter the field farther, a still greater shock will be sufficient to discourage this procedure. A field current of 3 volts or 4 volts is ample to divert a 30-in. salmon, it is contended, and yet will do the fish no harm even if it swim entirely through the field. The first of these devices are being installed at the various dams of the California-Oregon Power Company.

UNDERGROUND TRANSMISSION FOR ROCHESTER, N. Y.—Plans to clear the city of Rochester of light and power poles within five years by placing all electric cables within the city limits in underground conduits are announced by the Rochester Gas & Electric Corporation through Thomas H. Yawger, superintendent of the electrical department. The plan ties in with the company's project to remove all lines from weather hazards, Mr. Yawger said.

NORTHERN INDIANA PUBLIC SERVICE PLANS NEW POWER HOUSE.—Construction of a large electric generating station at Michigan City, Ind., on the lake front by the Northern Indiana Public Service Company will begin early in 1929, according to an announcement just made by the company, though operation will not begin until 1931. The first unit—a 60,000-kw. turbine—has been ordered and will be built by the Westinghouse Electric & Manufacturing Company. That part of the building to be erected next year will afford room for a second unit of the same size. The estimated cost of the initial construction is approximately $9,000,000. Plans for the construction of a generating station in Michigan City were announced originally in November, 1925, soon after the site was purchased. A large substation has been built there since that time and is an important distribution center.

PROVINCE OF ALBERTA AND CALGARY POWER COMPANY MAY BE RIVALS FOR GHOST RIVER POWER.—Dispatches from western Canada indicate that the Calgary Power Company is seeking a license for development of hydro-electric power on the Ghost River, which rises in the Banff National Park, north of Lake Minnewanka, in the Province of Alberta. The Calgary Power Company, which operates power plants on the Bow River, has greatly extended its service north and south along the "backbone of the province," from Lethbridge in the south toward Edmonton in the north, and has applied for the right to develop 75,000 hp. from the Spray Lake site, also in the national park. The situation is complicated by the fact that the natural resources of Alberta may soon be turned over by the Dominion government to the province, which may seek to develop a hydro system of its own.

# Recent Court Decisions

NOVEL CASE OF MIXED FEDERAL AND STATE JURISDICTION.—Levin and others brought suit against the Philadelphia Electric Power Company to restrain the operation of the transmission line from Conowingo until alleged damages to their property situated near the right-of-way had been ascertained and paid. In denying an injunction, the United States District Court for the Eastern District of Pennsylvania said that the plaintiffs' action was based (a) on an act of Congress according right of action to any one whose property is damaged by operation of the transmission line as distinguished from its construction, (b) on an easement owned by the plaintiffs in the land traversed, and (c) on the allegation that the defendant was threatening to break its covenants. This, the court said, brought about a novel case of mixed jurisdiction, since (a) belonged to the federal courts and (b) and (c) to the state courts. In such a case a United States court could assert jurisdiction over the whole proceedings, but this principle did not call upon it to grant the relief asked. The act of Congress involved gave no right to security in advance of judgment. (23 Fed. [2d] 508).*

POWER COMPANY RIGHTS IN NATIONAL FORESTS.—A suit brought by the United States against the Southern Power Company of South Carolina, which involved important problems in relation to control of lands embraced within national forest reservations, has been decided in the United States District Court of South Carolina in favor of the company, whose right to maintain power lines across tracts of land included within the Nantahala National Forest is sustained. The power company urged that the rights claimed by it were in existence at the time the forest was created and that the Weeks act, under which the land was taken to be a part of the national forest, does not empower the government to condemn and take easements and similar rights already used in public service; also that the power company relinquished its easement rights and permitted the government to take title to the land in its condemnation proceedings upon the agreement of the government to grant the company a permit to occupy the lands for the use of its power lines. The question of appeal is under consideration in the Department of Justice.

RIGHT TO CROSS POWER LINE WITH AËRIAL UPHELD.—In the New York Supreme Court, sitting in Albany County, $30,000 damages was granted by a jury to B. G. Troidle, a physician, against the Adirondack Power & Light Corporation because of severe burns said to have been incurred when 2,300 volts of electricity passed through his body after he had thrown an aërial wire over the company's power line at his camp at Ballston Lake. The plaintiff claimed that the insulation of the power line had been worn by the weather. Troidle testified that he had attached the wire to the garage at his camp and then thrown it over the power line, to run it to his cottage, loosening his hold on it at the same time; that the circuit formed when the wires came in contact flung the aërial wire back against him, and that when he tried to ward it from his face the 2,300 volts passed through various parts of his body, burning him in fourteen places. Dr. Troidle purchased his camp site from the Schenectady Railway Company, from which the Adirondack Power & Light Corporation obtained permission to string its wire overhead. The doctor's lease did not invalidate the company's right in this respect, it was shown. Lawyers believe it is the first instance where a court has upheld the right of a property owner to erect an aërial across the lines of a power company.

OREGON COUNTY COURT CLAIMS REGULATORY POWER OVER LINES BUILT UNDER BLANKET FRANCHISE.—Before the Marion County (Ore.) Court will grant an application for a blanket franchise to construct electric transmission lines throughout the district, it must first receive the assurance of the necessary authority not only to direct the location of proposed lines but to order that changes be made in routing following construction. This attitude was assumed by the court in connection with an application filed by the Molalla Electric Company, a subsidiary of the Portland Electric Power Company, and the operating field principally affected is that between the capital and Portland.

# Commission Rulings

SHOULD RATE REDUCTION IN METROPOLITAN DISTRICT APPLY OUTSIDE CITY LIMITS?—On its own motion the Oregon Public Service Commission ordered an investigation for the purpose of determining whether the reduction of electric light rates in Portland under the proposed merger plan of the utilities there would apply to service furnished by the operators outside of the metropolis. The Portland Electric Power Company, a utility engaged in intrastate business and a party to the proposal, renders service to the towns of Oregon City, Hillsboro, Salem and several smaller communities between the capital and Portland. In the plans introduced for the merging of the Portland plants nothing was mentioned regarding the consumers beyond the municipal limits wherein the merger was to be effected, and the commission decided to undertake an investigation to discover any possible discrimination.

FAIR DIVISION OF TERRITORY DOES NOT MEAN INDEFINITE PRE-EMPTION.—Approval was bestowed by the Public Utilities Commission of Colorado upon an agreement between the city of Fort Morgan and the Public Service Company of Colorado as to the division of certain territory to be served by their respective electric utility plants. When, however, the commission learned that, in addition to the territory which was to be served immediately, the Public Service Company had agreed to give the city of Fort Morgan the first chance to serve the customers in another area and that the city did not desire or consent to render the service at any time in the near future, the commission said: "The commission is of the opinion that it would be unwise and contrary to the public convenience and necessity to pre-empt this territory in favor of a utility which may never be willing to serve it. . . . Therefore no certificate authorizing such service should be issued.

# News About Men of the Industry

## C. J. Eaton Vice-President of Middle West Utilities

Chester J. Eaton, for the past nine years commercial manager of the Middle West Utilities Company, has been elected vice-president of that company, in charge of merchandising and sales. Mr. Eaton's promotion follows a wide experience in commercial work with public utilities and he is a recognized leader in the application of practical methods of developing increased use of electric services and in the popularization of appliances. Prior to taking charge of merchandising operations for the Middle West Utilities Company in 1919, Mr. Eaton directed the new-business activities of the Kentucky Utilities Company from 1912 to 1917 and of the Interstate Public Service Company from 1917 to 1919. He was associated with the Union Electric Company of Dubuque, Iowa, for two years and previous to that was engaged in commercial work for the Commonwealth Electric Company and the Chicago Edison Company before their consolidation into the present Commonwealth Edison Company.

*C. J. Eaton*

Mr. Eaton has been prominently identified with the activities of the Commercial National Section, N.E.L.A., and it is largely through his work as chairman that the committee on electrical advertising has organized and conducted its special training schools for central-station lighting salesmen. He is also chairman of the committee on employee use and selling of the electric range.

PAUL J. KRUESI of Chattanooga, Tenn., was elected president of the American Electrochemical Society at the recent convention held in Bridgeport, Conn. Mr. Kruesi's business interests have been centered in Chattanooga since 1902, when he became secretary-treasurer and manager of the American Lava Company. At the present time he is president and owner of that organization as well as president of the Chattanooga Electro Metals Company and of the Southern Ferro Alloys Company, not to mention other business interests of varied character. Before removing to the South Mr. Kruesi was identified with the General Electric Company, the Chicago Edison Company, the General Incandescent Arc Light Company, the Paragon Fan & Motor Company and the Wright Discount Motor Company. In addition to being prominent in the American Electrochemical Society, he is a member of the American Institute of Electrical Engineers, the American Iron and Steel Institute and other societies.

## I. W. Day New President of New England Division

Irvin W. Day, who was elected president of the New England Division of the National Electric Light Association at its annual meeting in Boston last week, is a well-known figure among the younger public utility executives of the Northeast. He was graduated from Cornell University in 1906 and spent several years in the steamship business. In 1912 he became assistant secretary and two years later secretary and treasurer of the United Electric Light & Water Company, Waterbury, Conn. Upon the merger of that company with the Connecticut Light & Power Company in 1917 Mr. Day was elected vice-president and a director of the merged company. When the Connecticut Electric Service Company was organized in 1925 as a holding company for the Connecticut Light & Power Company and a number of other public utilities of the Nutmeg state Mr. Day was also elected a vice-president and director of the latter organization. He is interested in and a director of a number of other companies and has been active in civic enterprises in the Naugatuck Valley. He has been an influential factor in the building up of a far-reaching Connecticut system noted for engineering excellence, commercial enterprise and sound public relations.

*I. W. Day*

## W. J. Serrill to Head Standardization Movement

William J. Serrill, assistant general manager of the United Gas Improvement Company of Philadelphia, has been elected to the chairmanship of the American Engineering Standards Committee. Mr. Serrill succeeds C. E. Skinner of the Westinghouse Electric & Manufacturing Company, who has been chairman of the standards committee for the past three years.

*W. J. Serrill*

Mr. Serrill has been prominent in standardization activities in the gas industry, and as representative of the American Gas Association he has been identified with the national standardization movement for several years. He has been active in the affairs of the Illuminating Engineering Society, having served as treasurer, vice-president and president. He is a graduate of the University of Pennsylvania. The vice-chairman will be CLOYD M. CHAPMAN, engineering specialist of New York City and representative of the American Society of Mechanical Engineers.

Among the members of the executive committee which will serve under Mr. Serrill are J. C. Parker and C. E. Skinner, representing the American Institute of Electrical Engineers; S. G. Rhodes, representing the electric light and power group, and S. L. Nicholson, representing the National Electrical Manufacturers' Association.

OWEN D. YOUNG, chairman of the board of directors of the General Electric Company, returned from abroad April 30 on the *Leviathan* after a short sojourn in Europe.

FRANK L. DAME, president of the North American Company, was elected a member of the board of directors of the Bank of America National Association April 30 at the first meeting of the enlarged institution formed by the merger of the Bank of America, the Bowery & East River National Bank and the Commercial Exchange Bank.

## *M. O. Troy Named Manager of Central-Station Department*

Matthew O. Troy has been appointed manager of the central-station department of the General Electric Company, Schenectady, according to an announcement made by President Gerard Swope. Mr. Troy has been identified with the General Electric Company continuously since 1897, when, following graduation from the University of Virginia, he entered the testing department at Schenectady.

He was later transferred to Lynn as foreman of transformer test and in 1898 he became associated with Elihu Thomson and Richard Fleming in pioneer work on constant-current transformers. In 1901 Mr. Troy was made assistant engineer of the Lynn alternating-current engineering department, subsequently entering the transformer sales department. In 1907 he became manager of sales of transformers, lightning arresters and regulators and in 1923, when the lighting department became the central-station department, Mr. Troy was named executive assistant manager. Mr. Troy has been a leader in the Pittsfield and Schenectady sections of the American Institute of Electrical Engineers and has been active in committee work in the National Electric Light Association and is a member of the board of governors of the National Electrical Manufacturers' Association.

*M. O. Troy*

---

**Theodore Beran**, who retired May 1 as commercial vice-president of the General Electric Company, as announced in the April 28 issue of the **Electrical World**, was tendered a testimonial banquet on the evening of May 2 at the Plaza Hotel, New York, by his former associates. The toastmaster of the occasion was Vice-President J. R. Lovejoy, and Gerard Swope, president, spoke on behalf of the company. On this occasion Mr. Beran was presented with a beautifully engraved tray by his associates. He is sailing on Saturday on the U.S.S. *Leviathan* for an extended trip through Europe.

**E. J. Condon, Jr.**, has terminated his connection as vice-president of the General Power & Light Company, the Arizona Edison Company and the Northern Michigan Public Service Company to engage in consulting engineering work with offices in Chicago. A graduate of Armour Institute, Mr. Condon has gained wide electrical experience in the course of his engineering career. As executive in charge of operation and management he developed successfully several central station properties in the Mountain Region and in the Middle West.

---

## *C. W. Stone Becomes Consulting Engineer in Schenectady*

C. W. Stone, manager of the central-station department of the General Electric Company, Schenectady, since its formation, has been appointed to the position of consulting engineer, having requested that he be relieved of his former responsibilities. As consulting engineer he will advise and assist in all new engineering developments for the General Electric Company and will also continue to act as consulting engineer for the R. C. A. Photophone, Inc.

Following graduation from the University of Kansas, Mr. Stone joined the Franklin Electric Company of Kansas City in 1894. Subsequently he was connected with the W. S. Hill Electric Company of New Bedford, Mass., and the Hancock Equipment Company of Boston before entering the drafting department of the General Electric Company. He held many important assignments in the engineering department and on the death of C. D. Haskins was made manager of the lighting department. In 1923 the lighting department was designated the central-station department and Mr. Stone continued as its manager. Mr. Stone has been active in the affairs of the National Electric Light Association, the American Institute of Electrical Engineers and the Association of Edison Illuminating Companies and is, in addition, a member of the American Society of Mechanical Engineers, the Illuminating Engineering Society, the Franklin Institute and other technical organizations.

## *Miss Zillessen Made Advertising Manager*

Clara H. Zillessen has been appointed advertising manager of the Philadelphia Electric Company after an affiliation with that utility which covers a period of fourteen years. Miss Zillessen was born in New York City and was educated there and in New Jersey. With the exception of two years as a fashion correspondent in New York her entire business life has been spent in the electrical industry. She started advertising work for the Philadelphia Electric Company in 1914 as a copy writer and in 1922 she was made assistant advertising manager. In addition to her executive duties with the Philadelphia utility, Miss Zillessen has developed broadening outside interests. She is chairman of the women's committee of the Pennsylvania Electric Association, a member of the Illuminating Engineering Society and of the Women Writers' Club. She has contributed numerous articles to newspapers and magazines and was the first winner of the Walter H. Johnson prize, awarded annually through the Pennsylvania Electric Association for the most constructive paper on central-station operation. The announcement of Miss Zillessen's appointment was made by William H. Taylor, president.

*Miss C. H. Zillessen*

# Obituary

**James A. Skinner**, who was connected with the General Electric Company for 30 years, died at his home in East Orange, N. J., April 16, after a long illness. During the war Mr. Skinner was supervisor of industrial relations and the manager's representative on the co-operative committee for the General Electric Company.

**William Carroll**, some years ago city electrician of Chicago, died at his summer home in Hartford, Mich., April 19, in his 77th year. Mr. Carroll retired from public office in 1912 after spending 38 years in city service, during seven of which he was city electrician. He was self-taught in technical matters, but his practical experience in the electrical work of the city made his services valuable and enabled him to conduct successfully the work of an important department through varying political administrations.

**Edwin Hulley**, president of the Hulley Electric Company, Philadelphia, died suddenly at his home in that city April 23. Mr. Hulley, who was 47 years of age, was born in Philadelphia and was affiliated with the Philadelphia Electric Company for 22 years. He was a district manager when he resigned to establish the company that bears his name. Mr. Hulley was very active in civic affairs.

# Financial and Statistical News

## *Money Rates No Check Prices Rise en Masse*

THE feature of significance in connection with the rise of call money to 6 per cent early this week was its ineffectiveness as a check upon speculative activity. Of course the increase was related closely to month-end payments, and an abundance of funds was immediately attracted from interior banks. But it is interesting to note that the 6 per cent rate had practically no restrictive effect just as the advance in Federal Reserve rates in certain districts was apparently ineffective. A complete revision of theory concerning the relation between money rates and speculative activity in the markets may soon be required.

The public utility stocks were in the limelight among the issues which advanced in the face of higher money rates. Power and light common stocks advanced this week in virtually all markets, and the gains have been well sustained. The present behavior of these issues supports the theory that the utility stocks have been considerably behind the market and are now advancing into a more proper alignment in relation to the market as a whole.

Among the more active issues this week Brooklyn Edison was again prominent, advancing twelve points, to 262; Consolidated of Baltimore gained eleven points, to 93; Edison of Boston advanced seven points, to 283; Metropolitan Edison five points, to 165; Middle West Utilities eleven points, to 152, and Southeastern Power & Light eight points, to 60. In addition there were a great many gains of from two to five points.

Prospects of dividend action in Radio Corporation common are increased by a statement attributed to President James G. Harbord that a dividend cannot reasonably be delayed much longer. It is probable that the matter will be taken up this week when the preferred dividend is being discussed.

## Loewenstein May Acquire Interest in Our Utilities

Apart from his interest in the development of hydro-electric power in the United States and Canada, nothing of unusual significance attaches to the recent visit to this country of Alfred Loewenstein, Belgian banker and financier. When interviewed with regard to the purpose of his visit, Mr. Loewenstein stated that he was interested in introducing the shares of the International Holding & Investment Company, a Canadian investment institution, into the New York market, and might possibly be in the market for certain utility stocks or properties.

Mr. Loewenstein denied the rumor that he intended to purchase control of the Brazilian Traction, Light & Power Company, adding that he was merely acting in an informal way to safeguard the interests of a group of bondholders of one of the company's subsidiaries.

## February Operations Show 8.1 per Cent Advance

FEBRUARY earnings of the electric light and power industry exceeded those of the corresponding month last year by 8.1 per cent, according to monthly reports received by the ELECTRICAL WORLD, and indicate a total for the country of $163,400,000. The rate of increase is materially larger than that of January, which, according to revised figures, amounted to 6.7 per cent, but against this must be balanced the fact that February this year had an extra day. Operating expenses, $64,200,000, also rose, but by only 6.7 per cent, this item being much less affected by the length of the month. Energy output was 6,390,701,000 kw.-hr., 12.0 per cent more than a year ago; 38.3 per cent came from water power and 61.7 per cent from fuel, the actual amounts being 2,445,189,000 and 3,945,512,000 kw.-hr. respectively, and the corresponding increases 12.5 and 11.6 per cent. As heretofore, the increasing efficiency in the use of fuel continues; the 11.6 per cent increase in output from fuels was attained with a 6 per cent increase in coal consumption, the 27 per cent increase in gas being roughly though not completely balanced by a 25.5 per cent decrease in fuel oil. In terms of coal equivalent, oil has fallen behind gas in importance.

In daily averages the month's operations broke all previous records; the revenue, $5,630,000, was higher than the average daily revenue for January, $5,560,000, which was the highest until that time; the output, slightly over 220,000,000 kw.-hr., passed the daily average for December, the previous highest, which was a little less than 217,000,000 kw.-hr., and coincides almost exactly with the estimated normal, 220,200,000,

*Data on "energy generated" are those collected and published by the United States Geological Survey for all public utilities minus such data as are collected on energy generated by electric railway companies, reclamation service and manufacturing plants. The data are, therefore, for the electric light and power industry only.

†1928 figures are only approximately comparable with those for 1927, because of changes in classification of certain plants.

based on past growth and observed seasonal variations. The average daily revenue, is, as in other recent months, somewhat below the normal, computed at $5,988,000. It is somewhat difficult to say how great is the effect, on this average, of the extra day. Operating expenses, averaging $2,210,000 a day, also reached a new maximum, but by only a small margin.

Regional analysis reveals averages not varying widely from the national, except in the South Central States where the returns indicate that the revenues exceeded those of February, 1927, by about 11 per cent. Similarly the regional averages of increase in energy output show somewhat less than the usual variation, the Southwest ranking highest, the South Atlantic Division lowest, with the others fairly close to the average for the country as a whole.

The purchase of energy for resale fluctuates more irregularly than does energy output or revenue, but in general is gradually rising. For several months it has been not far from 1,300,000,000, and that figure was again reached in February.

## Electric Supply in New Zealand

Of the electric supply in New Zealand 74.53 per cent is hydro, 23.20 per cent is steam, 1.42 gas and 0.88 oil, according to a recent letter from Charles Dash, chairman of the New Zealand Electric Power Board Secretaries Committee.

The water power that is available vastly exceeds the needs of the present population of 1,440,000, being estimated by government engineers at 4,887,030 hp., or 3.4 hp. per capita. Energy output in 1927 was equivalent to 310 kw.-hr. per capita; the power load is fast increasing in importance so that the peak demand now generally comes on the industrial load; in addition, 7 per cent of the customers cook by electricity. In dairying, milking machines increased from 1,310 in 1923 to 6,738 in 1927, though 9,000 machines are still fuel-driven. Other items are:

Capital investment approximates 19,000,000 ($92,000,000), made up of 7,000,000 government, 8,250,000 local bodies connected with government supply and 3,750,000 local bodies not connected with government supply; distribution line miles, 15,000; consumers, 228,000.

## Electric Power in Oil Fields

The use of electrically driven equipment in the oil fields has been found effective in each of the three most important operations in the industry, namely, production, pipe line pumping and refining. On the lines of the Oklahoma Gas & Electric Company this type of load has increased at a remarkable rate, according to data recently published by the company. Beginning with a contract covering a 30-hp. motor at the end of 1919, the energy sales to oil fields have grown as shown in the table above.

| | |
|---|---|
| 1920 | 829,088 |
| 1921 | 1,502,565 |
| 1922 | 2,689,457 |
| 1923 | 6,134,607 |

*As collected by United States Geological Survey. The data are for the electric light and power industry only.

# Electric Bond & Share Shows Larger Surplus

THE fact that both gross and net income of the Electric Bond & Share Company declined last year is due to the absence of certain substantial items of income, of a non-recurring nature prominent in 1925 and 1926, and also a decline in the volume of securities sold and construction work done for associated companies. Gross income fell off 7.6 per cent, to $18,513,299, and net income declined 15.4 per cent, to $11,899,326. The surplus at the close of December amounted to $21,039,062, having been increased from $16,766,140 due to reappraisement of securities and accounts and premium on sale of preferred stock, etc. Income figures for the past two years are shown in the accompanying table.

According to its annual statement the Electric Bond & Share Company anticipates a gradual shifting in the relative importance of some of the principal sources of income, the result of which should be better to stabilize the company's business and income. The rate of increase in the gross income derived from supervisory services rendered associated companies is expected to be less than heretofore, while the return on securities owned should become a much more important factor. One feature of interest in this connection is that the securities of the companies now associated with the Electric Bond & Share Company have become so well regarded by the investing public that the company is able to render the service of negotiating and selling these securities to investment bankers and others under a lower schedule of commissions.

INCOME STATEMENT

| | 1926 | 1927 |
|---|---|---|
| Gross income | $20,056,694 | $18,513,299 |
| Net income | 14,069,234 | 11,899,326 |
| Preferred dividends | 1,500,000 | 2,376,933 |
| Balance | 12,569,234 | 9,522,393 |
| Common dividends | 2,000,000 | *27,137,500 |
| Accumulated income | 33,940,648 | 16,325,541 |

* Includes special dividend on common stock in addition to the regular 8 per cent.

Total assets of the company as of Dec. 31, 1927, amounted to $124,195,442, but the market value is materially greater than the book value.

## Four New Issues Offered

Five-year 4½ per cent gold coupon notes of the Columbus Electric & Power Company were offered during the week ended May 3 to the amount of $2,500,000, the price being 97.80 and interest, to yield 5 per cent.

The Gulf States Utilities Company issued 30,000 shares of $5.50 dividend preferred stock at 98 and accrued dividend. Proceeds derived from the sale of these securities will be used to liquidate the floating debt of the company.

A Canadian issue appeared among the new offerings—the three-and-a-half million-dollar loan floated by the Nova Scotia Light & Power Company, Ltd. This issue was in the form of 5 per cent first mortgage 30-year sinking fund gold bonds, series A.

With the purpose of retiring its 7 per cent issue of cumulative preferred stock the Illinois Power & Light Corporation offered 364,740 shares of $6 cumulative preferred stock at $100 and accrued dividend.

## Allis-Chalmers Votes Stock Increase

At the annual meeting held at Wilmington, Del., May 3, the stockholders of the Allis-Chalmers Manufacturing Company voted to increase the authorized stock by $24,000,000, the proposed issue bringing the total authorized stock to $50,000,000. The plan calls for an increase from 260,000 shares of $100 par value to 500,000 shares of $100 par value. It is not contemplated that any portion of the proposed additional authorized capital stock will be issued at this time, but the board of directors deems it advisable to have such unissued stock available for possible requirements in connection with the company's future expansion and development.

## *Commercial and Municipal Operations in Canada*

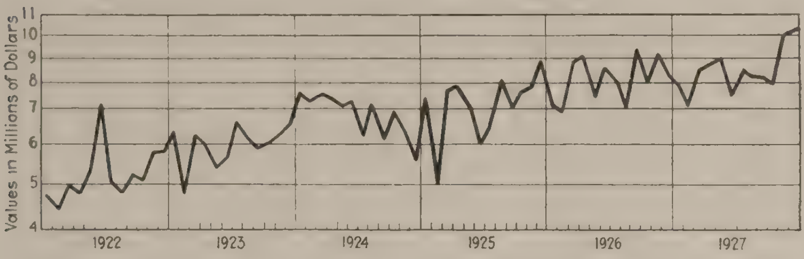
# Business News and Market Conditions

## Exports in 1927 Increase About 4 per Cent

Substantial increases are shown in the United States electrical equipment export trade in 1927. The value of exports in 1927 amounted to $102,340,129, which was the best since the record year of 1921. In 1926 electrical exports totaled $98,495,245. This increase is accounted for to a great extent by enlarged foreign markets for batteries, generators, fractional-horsepower motors, motor-driven household devices and washing machines. Exports of electric fans showed a small gain, while those for domestic heating and cooking devices declined.



*Exports of electrical machinery, equipment and supplies from the United States*
(Data supplied by the Bureau of Foreign and Domestic Commerce)

Exports to the Western Hemisphere amounted to $56,418,800, an increase of $2,994,800 over the preceding year. Canada is the largest consumer of our products and exports to that country showed an upward trend during 1927, the leading items being radio equipment. The next largest market in the Western Hemisphere was Argentina, whose imports of United States electrical equipment for 1927 amounted to $7,061,000, an increase of $1,857,400 over the preceding year.

Exports to European countries in 1927 amounted to $18,344,000, an increase of $3,960,200. Exports to Germany were valued at $1,391,800, an increase of $715,000. Shipments to Asia, Africa and Oceania showed a decrease of $3,140,000, part of which is accounted for by the large decrease of Japanese exports, which declined almost 50 per cent, or $4,239,000. Although exports to Australia, New Zealand and British India have decreased, these decreases are offset to a certain extent by an increase of trade with the Philippine Islands.

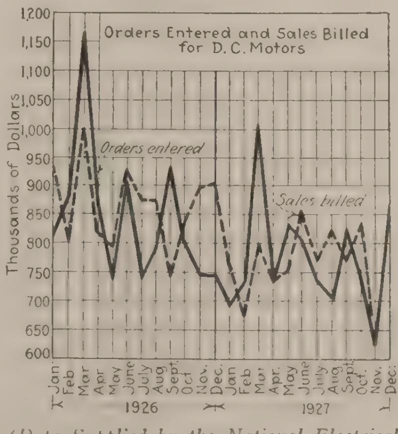
## Liege Exposition in 1930

Plans are well advanced in Belgium for the "International Exposition of Industry, Sciences, Applications and Ancient Walloon Art" to be held at Liége in 1930 in celebration of the centenary of Belgian independence. "Electricity" forms the thirteenth group under the classification of "grande industrie" and is subdivided in the following manner:

(a) Production and storage of electrical energy; (b) transmission of current; (c) transformation of current; (d) applications of electricity to (1) mechanics, (2) metallurgy, (3) chemistry, (4) transportation, (5) lighting, (6) domestic purposes, (7) telephony, telegraphy and television, and (8) the medical art; (e) methods of control and measurement.

Each of the divisions mentioned will be in turn subdivided and the entire field of electricity will thus be covered. The director of the exposition is Nello Breteuil, and its Liége offices are at 4 Place Saint-Lambert.

## Orders Entered and Sales Billed for D.C. Motors



*(Data Supplied by the National Electrical Manufacturers' Association)*

## Electric Industrial Trucks and Tractors

March shipments of electric industrial trucks and tractors, as reported to the Department of Commerce by the nine leading manufacturers in the industry, were 131, compared with 119 in February and 116 in March, 1927. The accompanying table gives the shipments for 1926 and 1927, month by month, as well as shipments for the first three months in 1928.

SHIPMENTS OF ELECTRIC INDUSTRIAL TRUCKS AND TRACTORS

| | Domestic | | | |
|---|---|---|---|---|
| 1926 | Tractors | All Other Types | Exports | Total |
| January | 21 | 86 | 4 | 111 |

## Orders for Electrical Goods

New orders booked during the first quarter of 1928, as reported to the Department of Commerce by 86 manufacturers of electrical goods, were $244,916,615, as compared with $239,999,298 for the last quarter of 1927 and $243,651,415 for the first quarter of 1927. The accompanying table gives the totals of bookings for each quarter since the beginning of 1923, not as a complete statement of the industry but as probably sufficiently representative to indicate the trend.

ORDERS FOR ELECTRICAL GOODS

| Quarter | 1923 | 1924 | 1925 | 1926 | 1927 | 1928 |
|---|---|---|---|---|---|---|
| First | $225,399,383 | $228,760,838 | $233,023,182 | $262,677,736 | $243,651,415 | $244,916,615 |
| Second | 240,542,824 | 221,167,876 | 227,502,652 | 248,000,075 | 236,427,121 | ........ |
| Third | 201,910,099 | 185,747,314 | 232,933,532 | 241,114,209 | *235,847,857 | |

| Total | $886,017,721 | $867,146,580 | $938,056,416 | $1,011,870,102 | $954,925,691 | ........ |

* Revised

# Market Conditions

VOLUME of business as well as prospects look good in the New England district. Small motor sales showed a substantial gain. In the Eastern district a slight decline in orders is noted, but there is an encouraging volume of inquiries. A 60,000-kw. turbo-generator was purchased by an Indiana power company. Better conditions are noted in the Southeast. Order for $475,000 worth of generating equipment and $25,000 worth of oil circuit breakers were placed for a hydro-electric development in Alabama. An industrial plant in Georgia ordered $60,000 worth of rock crushing and mining equipment and an aluminum plant in Tennessee ordered three 6,000-hp. water wheels.

Equipment for a steel rod mill was purchased in the St. Louis district at a cost of $130,000. A good demand for building construction materials is reported. In the Middle West business is improving. An order was placed for $500,000 worth of paper insulated lead covered cable. Line extension and construction work is in good volume. On the Pacific Coast sales of pumping motors and small distribution transformers are good. Machinery and power apparatus orders were varied and in steady volume.

## *Better Conditions Noted in the Southeast*

Conditions in the Southeast are better both in the central-station and industrial fields. Orders were placed for generating equipment approximating $475,000 and oil circuit breakers costing $25,000 for a hydro development in Alabama. Other good business is in more or less immediate prospect on general central-station apparatus, including some steam equipment. A large school in Tennessee ordered a turbine, stokers and condensers amounting to $45,000, while a small college in Georgia ordered lighting fixtures amounting to $3,500.

An industrial plant in Georgia has ordered $60,000 worth of rock crushing and mining equipment, $15,000 of this being for motors, while an aluminum plant in Tennessee ordered three 6,000-hp. water wheels. A steel mill in Alabama placed an order for four mine locomotives costing about $30,000 and a cotton mill in South Carolina purchased stoker equipment totaling $7,500. Small individual orders predominate in the industrial field, but the total volume of business is satisfactory and the most activity to be noted is in Alabama and the Carolinas. Orders for electrical materials, amounting to about $8,000, for a silk mill in Tennessee will probably be placed shortly and electrical equipment contracts on a bleachery in the Carolinas are in early prospect. Construction has started on the first $2,500,000 unit of a $10,000,000 rayon plant in Georgia. Municipalities are purchasing in reasonably good volume. A small town ordering line construction materials amounting to $2,000, while an order for "white-way" equipment, totaling $5,000, will probably be placed at an early date by another town. Purchases by contractors are increasing. Construction projects are as follows:

The Southern States Power Company, Fernandina, Fla., plans an expansion program to cost $100,000, including a substation on Jefferson Street. A. S. Andersen, 519 Twenty-eighth Street, West Palm Beach, Fla., and associates are organizing a company to build a cold storage plant, to cost $225,000. The Echota Cotton Mills, Calhoun, Ga., plan a plant unit to cost $100,000. The Baker County Power Company, Newton, Ga., will build a steam power plant at Moultrie, Ga. Leland, Miss., will receive bids until May 22, for equipment for a municipal power plant. The Mississippi Steel & Iron Company, Jackson, Miss., plans a mill to cost $100,000. The Planters Cotton Oil Company, Yazoo City, Miss., has authorized complete electrification of its plant.

The Nestles Food Company, New York, N. Y., plans a milk plant at Newton, N. C., to cost $200,000. Standard Looms, Inc., Spartanburg, S. C., plans a plant, for manufacture of textile machinery, to cost $175,000. The Tri-State Compress Company, Huston, Miss., will build a cotton compressing plant at Memphis, Tenn., to cost $300,000. The Pet Milk Company, St. Louis, plans a milk condensing plant at Abingdon, Va., to cost $200,000. The Alabama Power Company, Birmingham, plans a transmission line for service at Center Star, Killen, Shoal Creek Bridge, Ala., and vicinity. The Southeast Georgia Power Company, Alma, Ga., has acquired the municipal plant at Broxton, Ga. The Mississippi Power Company, Gulfport, Miss., has acquired the Richton Light & Power Company, Richton, Miss. The Virginia Public Service Company, Charlottesville, Va., has acquired the Stonewall Power Company, Manassas, Va.

## *Copper in Good Demand—Prices Firm*

The general tone of the non-ferrous metal markets is firm and a feeling of optimism prevails. Copper has again had a normal week as to volume of sales, with little or no shading of prices. Zinc has advanced slightly and sold in considerably larger volume than in either of the last two weeks. On the other hand, lead and tin have been quieter than usual, with a little weaker price level for the latter metal. The monthly average prices for copper, zinc, and silver have shown a gain now for two successive months. This tendency upward, though very gradual, shows no sign of abating at the beginning of May.

NEW YORK METAL MARKET PRICES

| | Apr. 25, 1928 Cents per Pound | May. 2, 1928 Cents per Pound |
|---|---|---|
| Copper, electrolytic...... | 14.00 | 14.025 |
| Lead, Am. S. & R. price | 6.10 | 6 10 |
| Antimony............. | 10 00 | 10.375 |
| Nickel, ingot........... | 35.00 | 35 00 |
| Zinc spots............. | 6.15 | 6.225 |
| Tin, Straits............ | 52⅛ | 51½ |
| Aluminum, 99 per cent... | 24.30 | 24.30 |

Base copper wire price May 2, 1928, 16 cents.

The copper market is virtually unchanged either in price or in volume of sales though there has been less tendency to offer the metal at concessions from the prices at which most of the producers have held for some weeks. Export sales are satisfactory and the price continues at 14½ cents. Sales of lead have been considerably below normal. No appreciable change is observed in the market although two sales of fair tonnage were reported below the prevailing levels of 6.10 cents, New York and 6 cents St. Louis. Several of the largest domestic producers oversold their supply of metal in April.

## *Slight Decline in Orders in Eastern District*

An encouraging volume of inquiries is reported in the Eastern district, but there is a noticeable decline in actual orders for primary equipment. An Indiana power company has contracted for a 60,000-kw. turbo-generator for delivery around the close of the year. A copper mining company in the Southwest is in the market for a 12,500-kw. unit, and is expected to place an order at an early date. A central-station company in northern New York has given a contract for cable of the medium voltage type, totaling about $15,000, and there is other business of this character in sight. Transmission apparatus also is in demand by several central-station companies in Pennsylvania and the South.

An order for switching equipment has been placed by a New York company at a price of $35,000. Transformer business continues rather spotty. One maker reports current business of lessened demand, with the bulk of the call for equipment of smaller capacity ratings; another producer says that things are fair in this line and has just contracted with a northern New York power interest for $100,000 worth. Electric railway business continues to lag. The Navy Department has ordered a turbine-gear drive for installation on a transport.

Industrial business is centered on motors at the present time and while orders are being received in reduced volume on individual account, fair gross sales are being recorded. Fractional units are in better demand than for several weeks past; one maker has secured a contract from a manufacturer of electrical apparatus for 1,000 1-hp. motors, totaling around $20,000. Control equipment sales are trending upward. Electric clock business is a feature of current activities and the improvement is expected to continue. A maker of time-pieces of this kind has placed an order for 15,000 induction motors, with an Eastern manufacturer, to cost about $50,000. Immediate construction operations in the Eastern district include the following:

The Purty Boat Works, Port Washington, L. I., will make additions to cost $125,000. The Agfa-Ansco Corporation, Binghamton, N. Y., will build a camera-manufacturing plant to cost $2,000,000. The Public Service Electric & Gas Company, Newark, N. J., plans a substation at Jersey City, to cost $75,000, and another at South Orange to cost $70,000. The New Jersey Port Commission, Camden, N. J., plans a marine terminal to cost $2,000,000. The Heimbach Baking Co., Allentown, Pa., will build an addition to cost $200,000. The American Rolling Mill Company, Middletown, Ohio, will build an extension to its Columbia mill at Butler, Pa., to cost $1,000,000.

The Board of Education, Pittsburgh, Pa., will receive bids until May 15, for equipment for a proposed trade school. The Celanese Corporation, Amcelle, Md., will add to its rayon mill at a cost of $1,500,000. The Procter & Gamble Company, Cincinnati, Ohio, will build a soap-manufacturing plant at Baltimore, Md., to cost $3,000,000. The Quartermaster Depot, Camp Holabird, Md., will receive bids until May 9, for 115 storage batteries. The Quartermaster General, Washington, D. C., is asking bids until May 18, for three 750-hp. Diesel engines for Fort Mills, P. I.

## *Pumping Motor Sales Active on Pacific Coast*

Machinery and power apparatus orders on the Pacific Coast include a 75-kva. generator, valued at $2,500, for a gas engine manufacturer; a 100-kva. gas engine generator, valued at $4,000, for a state polytechnic school; five large substation circuit breakers amounting to $17,500 for the Contracosta substation of the Great Western Power Company; two 700-hp. synchronous motors and exciter set, valued at $12,500, for a Utah copper company; a five-ton storage battery locomotive and charging set, valued at $7,000, for a Sierra gold mine, and four refrigerator type motors amounting to $9,000 for food packing plants in San Jose and Monterey.

Manufacturers report excellent sales of pumping motors and small distribution transformers. Power company inquiries cover fiber conduit, and pin type insulators for the Bay section. Two carloads of assorted poles were ordered for Sacramento, and one carload of 7,500-volt line switches for Los Angeles. An unusual inquiry for San Jose delivery covers $1,000 worth of large rubber covered cable. Street lighting business includes $48,300 worth for Santa Barbara and a number of good prospects.

The city of Seattle will shortly buy machinery for a 25,000-kw. expansion of its Gorge Creek hydro-electric plant at a cost of about $500,000. Buhl, Idaho, plans an 800-hp. municipal plant to cost $150,000. The Washington Water Power Company plans a 110,000-volt line from Chelan to Wenatchee. Motor sales were light, the majority being small units for irrigation use and orchards. Construction projects are as follows:

The Los Angeles Gas & Electric Corporation, Los Angeles, plans an automatic substation on South Woodland Avenue, and another on Lawrence Street, to cost $75,000. The Southern Pacific Railroad Company plans shop extensions at Sacramento, Calif., to cost $2,000,000. The Oregon Short Line Railroad will add to its steam power plant at Pocatello, Idaho, to cost $100,000. Lima, Mont., has authorized a municipal power plant. The Northwestern Pulp & Paper Company, Astoria, Ore., will build a mill to cost $2,000,000. Modesto, Long Beach, and Los Angeles, Calif., plan ornamental lighting systems.

## *Small Orders in Good Volume Mark New England Trend*

While heavy equipment sales have fallen off in New England and industrial activity has lessened in a number of branches, the volume of material moving and the prospects ahead are favorable. Small motor sales showed a substantial gain, and a large amount of new construction material was ordered. Industry, through reorganization of plants, is an active factor in buying. Service expansion has provided a good demand for transformers, meter sales are strong, small orders for switch and control equipment are noted, and specialties are quite active, among which may be included power tools, the sales of which are now very steady. Welding equipment and electric furnaces also are in demand.

Interior electric wiring projects are in advance over those of last year. Manufacturers of loom and paper mill machinery are busy and planning for Southern installations. Artificial ice making is receiving much attention. Among the installations planned should be added one for the Chelsea district as announced by the Boston Ice Company. The bill providing for additional water supply for Springfield, Mass., which includes plans for a 20,000 hp. development on Cobble Mountain has been signed. The Marborough Chamber of Commerce announces plans for the establishment of three new shoe industries in that city.

## *Business Improving in Middle West*

Business in the Middle West is improving. The consensus of opinion is that April sales were favorable and the outlook is promising. Considerable new building construction is under way, particularly in the suburban districts, and general employment conditions are improving. Industrial activity is somewhat spotty. Contemplated expenditures of the various railroads are large and should tend to increase the volume of business. A very large amount of line extension and construction work is being done by the various utility companies, one of the most interesting being the construction of a hydro-electric plant on the Rock River at Rocton by the Wisconsin Light & Power Company, at a cost of $250,000. Among the orders placed were one for paper insulated lead covered cable valued at more than $500,000, disconnecting switches valued at $24,000 and several construction orders totaling $60,000. Construction projects are as follows:

The Chicago, Burlington & Quincy Railroad Company, Chicago, plans a power plant to cost $80,000. The Frank Foundry Company, Moline, Ill., plans an addition to cost $200,000. The Rockford Paper Box Company, Rockford, Ill., will build an addition to cost $125,000. The Showers Brothers Manufacturing Company, Bloomington, Ind., plans an addition to its kitchen cabinet plant, to cost $100,000. The Northern Indiana Public Service Company, Hammond, Ind., plans a steam power plant at Michigan City, Ind., to cost $5,000,000. The Grand Trunk Railway System will build an engine house at Ferndale, Mich., to cost $150,000. The Macklin Company, Jackson, Mich., plans extensions in its grinding wheel plant, to cost $100,000.

The Great Northern Railway Company plans shops at Grand Forks, N. D., to cost $125,000. The Cleveland Electric Illuminating Company, Cleveland, is negotiating for the purchase of the municipal plant at Ashtabula, Ohio. The Edward J. Shannon Company, Cincinnati, plans an addition to its paint manufacturing plant, to cost $75,000. The Andrew Jergens Company, Cincinnati, will add to its soap manufacturing plant, to cost $200,000. Thompson Products, Inc., Cleveland, plans additions to its plant to cost $250,000. The E. M. Hulse Furniture Company, Columbus, Ohio, plans a plant to cost $275,000. The Appleton Coated Paper Company, Appleton, Wis., will build an addition to cost $130,000. Elmwood Park, Ill., Ames, Keokuk and Boone, Iowa, and Lincoln, Neb., plan ornamental lighting systems.

## *Steel Rod Mill Places Order in St. Louis District*

Manufacturers in the St. Louis district report the demand for stock sizes of apparatus has been considerably below normal but the belief is unanimous that the condition is only temporary. An order consisting of motors, transformers and control equipment for a steel rod mill was placed at a cost of $130,000. Another order was for a 100-hp. motor and other equipment amounting to $6,000. Jobbers report a good demand for building construction materials but no marked activity in line construction equipment. The general volume of jobbing business is considered satisfactory and the prospects look favorable. Construction projects are as follows:

The Peoples Utilities Company, Clinton, La., plans a power and ice plant at Clinton, La. The Quaker Oats Company, Chicago, will build a mill at St. Joseph, Mo., to cost $2,000,000. The General Tire & Rubber Company, Akron, Ohio, plans a factory branch at Kansas City, Mo., to cost $200,000. The Brown Cracker & Candy Company, San Antonio, Tex., plans a plant to cost $300,000. The Public Service Company of Oklahoma, Tulsa, Okla., will build a transmission line between Vinita and Jay, Okla. Bethany, Mo., plans an ornamental lighting system.

# Activities of the Trade

## Hubbard & Company Make Organization Changes

Two additions to the Pittsburgh plant of Hubbard & Company, manufacturer of pole line hardware and Peirce construction specialties, are now nearing completion. During May it is the intention of the company to move the Niles operation to Pittsburgh. The following organization changes also have been announced by C. L. Peirce, Jr., vice-president in charge of the electrical materials business of the company:

Joseph V. Smith, formerly Pacific Coast manager, is now Eastern manager in charge of the Pittsburgh plant and the territory served by it; W. R. Pounder continues as Central manager in charge of the Chicago plant and the territory it serves; Norris C. Husted, formerly manager of the Niles plant, has been made Pacific Coast manager in charge of the Emeryville, Cal., plant and the Pacific Coast territory; Wallace W. Glosser, formerly sales manager of the Verona tool works, has been made New York district sales manager with headquarters at 30 Church Street, New York City, and Thomas J. Farrell, formerly sales manager of the Universal Sales Company, has been made special representative in the New York district.

## Copeland Products to Double Manufacturing Facilities

Construction of additional manufacturing facilities now under way by the Copeland Products, Inc., Detroit, will virtually double the production of the company's electric refrigerators. Property adjoining the present factory has been leased and it is expected that it will be ready for occupancy about June 1. "Rapid growth in demand for the Copeland product has made it necessary to enlarge our plant at an earlier date than we anticipated," said W. D. McElhinny, vice-president in charge of sales. "Our present plant has been credited by manufacturing experts with unusual efficiency and we had thought its capacity sufficient to take care of our requirements for several years yet. The Copeland business showed a 40 per cent increase in 1927, as compared with a 20 per cent average increase for the industry and in the first quarter of 1928 showed a further increase of 45 per cent over the same quarter of the previous year.

"It is not in anticipation of business that may develop, but to care for orders already on hand and immediately in sight that this plant expansion has been decided upon. However, in keeping with Copeland's policy of holding fixed assets at a minimum figure, additional facilities are being leased rather than purchased. Recent additions to the Copeland line have practically doubled its sales possibilities in the household, commercial and apartment house fields. We are also facing the necessity of caring for a big business on our new "Silica Gel" units, just in process of introduction, which will embrace everything in the field of commercial refrigeration."

---

The Leonard Refrigerator Company, Grand Rapids, Mich., announces that 3,782 Leonard refrigerators were shipped in a 43-car train in one day by the company over the Pennsylvania Railroad to dealers at various points through the United States, Canada and Mexico.

Landers, Frary & Clark, New Britain, Conn., manufacturers of electrical appliances, announce a new product, the "Univac" electric cleaner, selling for $34.50, with attachments $5 extra.

The Penn Electric Switch Company, Des Moines, Iowa, announces that it has taken over the Wilboken Manufacturing Company of Milwaukee, which will be continued for the present as a division of the Penn Electric Switch Company.

The Wright Manufacturing Company, Lisbon, Ohio, manufacturer of chain hoists, trolleys and cranes, announces the sale of its business and trade name to the American Chain Company, Inc., Bridgeport, Conn. There is no anticipated change in policies or sales organization of the company. H. F. Wright and W. F. Wright will continue in charge of sales and production of Wright products.

The National Lamp Works of the General Electric Company, Nela Park, Cleveland, is offering a stereopticon projection film on "Home Lighting" and a talk to accompany it. This illustrated talk is particularly useful to organizations which are interested in relighting-the-home activities. It portrays the principles of good home lighting and gives practical suggestions for properly lighting each room in the home. Copies of the film and talk are available at a cost of $5. It was prepared by M. Luckiesh of the lighting research laboratory of the company.

The General Electric Company has received an order for carrier-current communication equipment for use in conjunction with the Big Creek line No. 3 which will connect the Magunden and Gould substations of the Southern California Edison Company. The equipment will include ten coupling capacitors and the latest type of vacuum-tube carrier-current apparatus. The Southern California Edison Company previously had in operation a similar system on two of its 220,000-volt transmission lines.

The Dampney Company of America, Hyde Park, Boston, announces that the sale of its "Apexior" protective coatings for power plant equipment will be handled in southern Texas by the Maintenance Engineering Corporation, 2000 Harrington Street, Houston.

S. A. Weiss & Company announces its removal to Room 510, 342 Madison Avenue, New York City. The company represents the Minerallac Electric Company of Chicago, Thoner & Martens of Boston, the J. L. Gleason Cable Reel Company of Boston and the Line Material Company of Milwaukee.

The A. J. Lindeman & Hoverson Company, Milwaukee, manufacturer of electric cooking and heating appliances, announces that the new L & H electric ranges are now being made in color. Shades of Alice blue, Arabian tan, Nile green, Oriental yellow and coral red with a background of old ivory are available.

The General Electric Company is now issuing specifications in which the G.-E. wiring system is applied to apartment houses and apartment hotels. These specifications show the wiring layouts for typical apartments of the one-story and two-story type, also the wiring for the simplex, duplex and studio designs.

The Foxboro Company, Inc., Foxboro, Mass., manufacturer of indicating, recording and controlling instruments, announces a new push-button chart hub for use with its recording instruments. It accurately centers the chart and can be easily detached.

## Packard Electric Uses Plane in Sales Work

This Stinson-Detroiter six-passenger cabin monoplane will be used in sales work by N. A. Wolcott, president; W. F. Parker, general manager of the transformer division, and engineers of the Packard Electric Company.

# New Equipment Available

## Air Filter

The "Simplex" air filter developed by the National Air Filter Company, Chicago, consists chiefly of a large cylindrical drum which is closed at one end and carries the filtering medium on the outside surface of the cylinder. A segment of the drum which can be rotated is always immersed in oil. The filtering medium comprises layers of expanded metal for pre-cleaning and mats of heavy twisted copper ribbons of specially woven fabric wound layer upon layer for the final stage.

Under average conditions the drum is turned one-fifth of its circumference once a week and this immersion period gives the oil ample time to clean the filters thoroughly by solvent action. The company states that the "Simplex" filter combines the features of its "Rotary" and "Phoenix" air filters, but does not displace either of them. Standard sizes range from 800 to 40,000 cu.ft. per minute, and by using additional units any capacity can be secured.

## Portable Oscillograph

An improved type of portable cathode ray oscillograph for use in making laboratory and field measurements of transient electric phenomena has been announced by the General Electric Company. The unit is entirely self-contained and requires only a source of 110-volt alternating current to operate it. The company states that although extremely accurate measurements are possible with the new instrument it is ruggedly constructed and can be handled successfully with only the ordinary care required by other portable laboratory equipment. The instrument consists of two units, each mounted on a separate truck. The first unit contains the photographic recording apparatus and high-vacuum pump, while the second includes the rough vacuum pump, synchronous switching mechanism and cooling water system. The two units together weigh about 700 lb. and each occupies about the same amount of space as an office desk.

The oscillograph is of the high-voltage cold cathode type, operating on 30,000 to 60,000 volts, supplied by a transformer. The tube is built into the end of a metal bell which contains the film holder and the whole interior is exhausted of air during operation. When excited the cathode of the tube emits a stream of electrons which traverse the length of the vacuum chamber and impinge upon the film. The stream is acted upon by a number of electromagnetic and electrostatic fields imposed on it by means of several sets of electromagnets and parallel plates, so that both voltage and current waves may be recorded. When transients of very short duration are to be photographed the beam is given an undulatory path across the film by the action of an electrostatic field supplied by a high-frequency oscillator included in the unit. This greatly increases the length of the ray path and also furnishes a timing wave by which to measure the duration of the transient. The frequency of this timing wave may be adjusted for any value between 20,000 and 1,000,000 cycles per second and its voltage may be given any value from 10 to 1,000 volts, depending on the wave amplitude desired.

The oscillograph finds its greatest use in recording transient electric phenomena with wave fronts equivalent to frequencies from 10,000 to 1,000,000 cycles per second, although frequencies of 100,000,000 cycles have been recorded. Some of the classes of work for which the instrument is especially fitted are: Volt-ampere studies of lightning arresters; recording of transient phenomena during switching on power lines; volt-ampere studies of mercury-arc rectifier characteristics; measurement of power amplifier characteristics, and measurements of pressures and time intervals along a gun barrel with the movement of a bullet.

## Switchboard Wire

An asbestos and varnished cambric insulated switchboard wire, with a smooth outer cotton braid which can be furnished in either gray or black, has been placed on the market by the Rockbestos Products Corporation, New Haven, Conn. This switchboard wire is especially adapted for wiring switchboards in power plants and substations. The wire consists of a tinned copper conductor insulated with two layers of varnished cambric, 30 units of felted asbestos saturated with a flameproof and moisture-resisting compound and an outer covering of gray or black flameproof cotton braid. It is said that the braid, which is closely woven, will not break or open on sharp right-angle bends.

**Insulator.**—A line of 6,600-volt and 8,800-volt insulators in color has been placed on the market by the Corning Glass Works, 369 Lexington Avenue, New York. The insulators are known as the marker type and are intended for the purpose of identifying low-voltage distribution lines.

**Binding-Wire Tension Indicator.**—A device for use in the repair of railway and industrial haulage motor armatures has been developed by the General Electric Company. This device indicates the exact strain or tension in pounds that is applied to the steel binding wire by the binding machine or lathe and provides a simple means of keeping track of this tension throughout the full operation of binding up the armature. By its use the binding wire will not be stressed beyond the elastic limit or tensile strength of the steel and will be kept under uniform tension during the process of winding it in place.

## Starters for D.C. Motors

A complete new line of direct-current motor starters for general purpose applications has been introduced by the General Electric Company. These starters are designed to provide definite time acceleration for constant- and adjustable-speed motors and are divided into five types, bearing the designations CR-4065, CR-4066, CR-4166, CR-4068 and CR-4168. One of the principal advantages of the new design is the fact that, despite a reduction in size, the number of accelerating points has been increased. An improved appearance is secured by the use of drawn-shell inclosing cases.

The CR-4065 starter is a constant-speed type for general purpose applications and the CR-4066 is the same type with the addition of dynamic braking. The CR-4166 is an adjustable-speed type with dynamic braking and full-field features. The CR-4068 is a constant-speed type, reversing, with dynamic braking. The CR-4168 is an adjustable-speed type, reversing, with dynamic braking and full-field features.

On those starters provided with dynamic braking a small relay is used to prevent the solenoid from being re-energized until the motor has come to rest. The contacts of this relay are connected in the pick-up circuit. Thermal overload protection is provided by means of single-coil relays designed for overload protection and having a thermal capacity to stand high inrush currents. These relays operate only in extreme conditions and serve as a warning to the operator that the motor or wiring requires attention.

## Disconnecting Switches

A line of high-tension reversible and interchangeable disconnecting switches has been placed on the market by the High Tension Company, 149 Broadway, New York City. All switch bases are of the channel type and all switches have double blade construction. Switches up to and including 22,000 volts have the U type blade; switches for 33,000 volts and above have the truss type.

The salient features pointed out by the manufacturer are: Reversible standard parts for inverted, upright or vertical mounting; interchangeable insulator units with cemented or adjustable non-cemented caps and pins; mounting holes symmetrical; offset pulling ring accessible at any angle; positive locking device; full-floating, self-aligning adjustable double pressure contacts; double switch blades; U-bolt type of clamp terminals; switch blade stops at 90 deg or 135 deg., and the elimination of tapped holes.

# Electrical Patents

*Announced by U. S. Patent Office*

(Issued April 17, 1928)

**16,935 (reissue).** ELECTRICAL STEAM GENERATION; T. H. Noll, Bronx, N. Y. App. filed Aug. 31, 1923.

**1,666,065.** MAGNETIC MOTOR; O. R. Anderson, Pasadena, Calif. App. filed April 1, 1924.

**1,666,089.** CONNECTER FOR ELECTRIC CIRCUITS; H. C. Foster, Connersville, Ind. App. filed July 25, 1927. Multiple circuit socket adapted to insure contact for three or more pairs of terminals.

**1,666,129.** TIME SWITCH; W. A. Frantz, Cleveland, Ohio. App. filed Jan. 21, 1924.

**1,666,223.** ELECTRIC-FIXTURE SUPPORT; W. Symmes, San Francisco, Calif. App. filed Oct. 23, 1922.

**1,666,247.** ELECTRIC CORD SWIVEL CONNECTER; C. Schuldt, Des Plaines, Ill. App. filed March 27, 1925.

**1,666,248.** THREE-WAY LAMP SOCKET; C. Schuldt, Des Plaines, Ill. App. filed July 22, 1925.

**1,666,281.** MAIL BOX; A. E. Deibert, Seattle, Wash. App. filed June 4, 1927. With an electric signal, as a bell.

**1,666,282.** PRESSURE-FLUCTUATING ALARM FOR MINES; R. C. Fagan, Spangler, Pa. App. filed Oct. 29, 1924.

**1,666,309.** MAGNOMETER; J. N. Ray, Newark, N. J. App. filed Nov. 26, 1924. Apparatus for testing the magnetism of electromagnetic sound reproducing devices.

**1,666,320.** LOCK-CONTROLLED ELECTRIC SWITCH; F. J. Watts, Bronson, Mich. App. filed Aug. 3, 1927.

**1,666,338.** ELECTRIC SWITCH; G. J. Meuer, Milwaukee, Wis. App. filed Jan. 18, 1926. Toggle type.

**1,666,339.** LUMINESCENT FUSE PLUG; L. F. Miller, Minneapolis, Min. App. filed Oct. 22, 1926.

**1,666,351.** ELECTRIC STRIKING MECHANISM; S. Rollin, Tulle, France. App. filed March 8, 1927.

**1,666,411.** ELECTRIC CONNECTER SOCKET; H. D'Olier, Jr., Bridgeport, Conn. App. filed Dec. 14, 1925.

**1,666,433.** SYSTEM OF ELECTRIC DISTRIBUTION; B. S. Weinfield, Schenectady, N. Y. App. filed June 28, 1926. For automatically controlling the connections and operation of a source of current whereby it is connected to a load circuit only under certain predetermined conditions, and whereby its output is limited to a safe value under abnormal load conditions.

**1,666,435.** SYSTEM OF ELECTRIC DISTRIBUTION; H. Bany, Scotia, N. Y. App. filed Jan. 8, 1926. An arrangement for controlling the operation of the interconnecting dynamo-electric units upon the occurrence of a reversal of energy flow.

**1,666,452.** GENERATOR FOR ELECTRIC-ARC WELDING; M. M. Irvine, Glasgow, Scotland. App. filed Feb. 15, 1927.

**1,666,457.** BRUSH LIFTER FOR ELECTRIC MOTORS OR THE LIKE; G. H. Leland, Dayton, Ohio. App. filed March 22, 1926.

**1,666,459.** BRUSH-LIFTING MECHANISM FOR ELECTRIC MOTORS OR THE LIKE; G. H. Leland, Dayton, Ohio. App. filed July 13, 1927.

**1,666,470.** ELECTRIC SWITCH; D. A. Sanford, Deceased, late of Washington, D. C. App. filed March 27, 1924. For attachment to the under surface of the floor of an elevator car and to be operated by the foot to energize an electro-magnet.

**1,666,471.** SYSTEM OF ELECTRIC DISTRIBUTION; H. T. Seeley, Schenectady, N. Y. App. filed Feb. 17, 1926. Comprising a supply circuit and a load circuit interconnected for controlling the operation of the inter-connecting units upon the occurrence of a reversal of energy flow.

**1,666,473.** HIGH-VOLTAGE DIRECT-CURRENT SYSTEM; J. Slepian, Swissvale, Pa. App. filed Feb. 26, 1921.

**1,666,498.** FLOAT-OPERATED ELECTRIC-SWITCH-ACTUATING MECHANISM; C. W. Lindemann, Chicago, Ill. App. filed April 9, 1926.

**1,666,546.** ELECTRIC LIGHTER FOR CIGARS, CIGARETTES, ETC.; S. L. Wolfson, Meriden, Conn. App. filed Feb. 18, 1928.

**1,666,588.** ELECTRIC MOTOR; M. Andis, Racine, Wis. App. filed June 26, 1926. Intended to develop light power under circumstances where considerations of size and weight are important.

**1,666,589.** ELEVATOR SIGNAL SYSTEM; C. W. Bassett, Montclair, N. J. App. filed April 17, 1926.

**1,666,639.** HOSPITAL SIGNAL SWITCH; J. O. Cadieux, Meriden, Conn. App. filed May 6, 1925.

**1,666,675.** CIRCUIT MAKING AND BREAKING DEVICE; T. Zweigsberck, London, England. App. filed Dec. 20, 1923. An electro-magnetically operated circuit breaker having an independently, mechanically operated mechanism adaptable for conjoint action with the electro-magnetic mechanism to close the circuit.

**1,666,680.** DYNAMOMETER; O. E. Buckley, Maplewood, N. J. App. filed Dec. 30, 1922.

**1,666,697.** DIATHERMIC APPARATUS; G. Grossmann, Berlin, Germany App. filed Oct. 7, 1927.

**1,666,724.** INCLOSED ELECTRIC SWITCH; D. T. Wadsworth, Cold Springs, Ky. App. filed Aug. 15, 1924. Meter service switch.

**1,666,729.** ELECTRIC FIXTURE; W. G. Biek and G. D. Rice, Dowagiac, Mich. App. filed July 20, 1927. Attachment plug adapted to be used in floors covered with rugs, the connection being made through the rug.

**1,666,762.** SEPARATOR FOR THE ELECTRODES OF ELECTROLYTIC CELLS; J. L. Woodbridge, Philadelphia, Pa. App. filed July 12, 1927.

**1,666,763.** SWITCH; G. A. Yanochowski, La Grange, Ill. App. filed May 31, 1924. Horn button.

**1,666,816.** AIR CIRCULATING AND HEATING APPARATUS; P. R. Falk, New York, N. Y. App. filed Nov. 22, 1926.

**1,666,831.** ELECTRIC HEATER; C. Pandolfo, Montevideo, Uruguay. App. filed Nov. 3, 1926.

**1,666,876.** LAMP FOR USE ON MOTOR VEHICLES AND FOR OTHER PURPOSES; S. L. Price, London, England. App. filed Jan. 17, 1923.

---

Information on foreign patents can be obtained through the nearest district office of the Bureau of Foreign and Domestic Commerce, Department of Commerce.

# New Trade Literature

FURNACE TYPE TERMINAL MOUNTINGS.—The Globar Corporation, Niagara Falls, N. Y., is distributing bulletin D, giving details of standard furnace type "Globar" terminal mountings. A drawing shows a typical cross-section through a furnace equipped with "Globar" electric heating elements, and detail drawings show the "Globar" terminal and mounting assembly, self-cooled and water-cooled. The bulletin also contains instructions for replacing "Globar" electric heating elements while the furnace is in operation.

LIGHTING UNITS AND FLOODLIGHTS.—Bulletin GEA-359A issued by the General Electric Company, Schenectady, N. Y., describes and illustrates the "Novalux" ornamental lighting units for street lighting. The company also is distributing bulletin GEA-161B covering searchlight and airport lighting, including floodlighting projectors, incandescent searchlights and aviation beacons. The bulletin covers the application of floodlighting to buildings.

FEEDER EQUIPMENT FOR MINING SERVICE.—Leaflet No. L 20,115-A, issued by the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., covers its automatic direct-current feeder equipment for mining service.

GROUNDS.—"Grounding Facts" is the title of a booklet issued by the Paragon Electric Company, 37 West Van Buren Street, Chicago. While the booklet gives information on Paragon grounds, directions for their installation etc., it is virtually a treatise on the general subject of grounding and contains information concerning the grounding of transformer secondaries, transformer neutrals, protection of station equipment, feeder circuits, arc-lighting circuits, trolley cirouits, railway signal installations, etc.

LIGHTNING ARRESTERS.—A booklet issued by the Electric Service Supplies Company, Seventeenth and Cambria Streets, Philadelphia, entitled "The Preferred Lightning Arrester of Today—Why?" is the seventh of a series describing the technical features of the crystal valve lightning arresters as they apply to modern lightning protection.

STARTERS.—The Monitor Controller Company, Baltimore, is distributing bulletin No. 112, covering the Monitor "Thermaload" starter designed for any type of drive where single-phase or polyphase motors are connected across the line. It contains a table of ratings, dimensions and weights of the Monitor starters and a table of the ampere rating of the thermal units to be used with induction motors.

TRANSMISSION MACHINERY.—Catalog No. 22 issued by Winfield H. Smith, Inc., Springville, N. Y., describes and illustrates its line of speed reducers, hangers, pillow blocks and other light power transmission machinery.

MOTORS.—The General Electric Company, Schenectady, N. Y., has issued a bulletin describing its standardized type MD-400 mill motors. Illustrations are given showing a few standard arrangements and some of their many applications.

INSULATING MACHINES.—Bulletin No. 332 issued by John Royle & Sons, Paterson, N. J., describes and illustrates its perfected insulating machines patented for applying die-formed rubber or plastic coatings upon electric conductors and other materials. The bulletin covers the features of construction and contains specifications covering the various machines.

MOTORS.—Bulletins GEA-752 and GEA-894 issued by the General Electric Company, Schenectady, N. Y., describe and illustrate its type BD constant and adjustable-speed direct-current motors and type CD adjustable-speed direct-current motors.

COMPRESSORS AND VACUUM PUMPS.—The Ingersoll-Rand Company, 11 Broadway, New York City, is distributing bulletin No. 3150, in which it describes and illustrates the class ER and FR compressors and vacuum pumps suitable for machine shop, factory, foundry, mine, quarry and power plants, also for air-lift pumping, liquid agitation and gas distribution. Various photographs show the detailed construction of the machines.

CONTROL EQUIPMENT AND BRUSHHOLDERS.—The General Electric Company, Schenectady, N. Y., has issued bulletin GEA-308A, describing and illustrating its arc suppressor plates for drum controllers. The company also is distributing the following bulletins GEA-934, covering the CR7896 automatic throw-over panels; GEA-835A, covering the CR4066, CR4068, CR4166 and CR4168 direct-current magnetic controllers for constant and adjustable-speed motors; GEA-948, describing the CR4065 direct-current magnetic controllers for constant-speed motors; GEA-950, covering the CR1028 alternating-current inclosed starting rheostats used in conjunction with primary switches for slip-ring induction motors, and GEA-760A and GEA-838A, covering its improved brush-holders and ventilated covers for GE-275 and GE-247 railway motors, respectively.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered, further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number:

Purchase is desired in Melbourne, Australia (No. 30,912), of battery chargers.

Purchase is desired in Sheffield, England (No. 30,913), of battery-charging panels.

Purchase and agency are desired in Otanes, Spain (No. 30,895), for electric galvanizing apparatus.

An agency is desired in Munich, Germany (No. 30,908), for household electrical appliances, especially washing and ironing machines.

Purchase or agency is desired in Montreal, Canada (No. 30,909), for electric lamps, standards and shades and another (No. 30,935) for electric surfacing machines.

Purchase and agency are desired in Melbourne, Australia (No. 30,910), for electric hand vacuum brushes for automobile upholstery.

An agency is desired in Frankfort, Germany (No. 30,876), for electric washing machines.

Purchase is desired in Temuco, Chile (No. 30,931), of wiring supplies and fixtures.

---

Any manufacturer desiring to establish agencies abroad may consult with the nearest district office of the Bureau of Foreign and Domestic Commerce, Department of Commerce, where data on available agencies throughout the world are on file.

# Business Facts for Electrical Men

**Selected Statistics Presented Graphically for the Use of All Interested in Analyzing the Trend of the Electrical Business**

## South's Rapid Increase in Industrial Activity

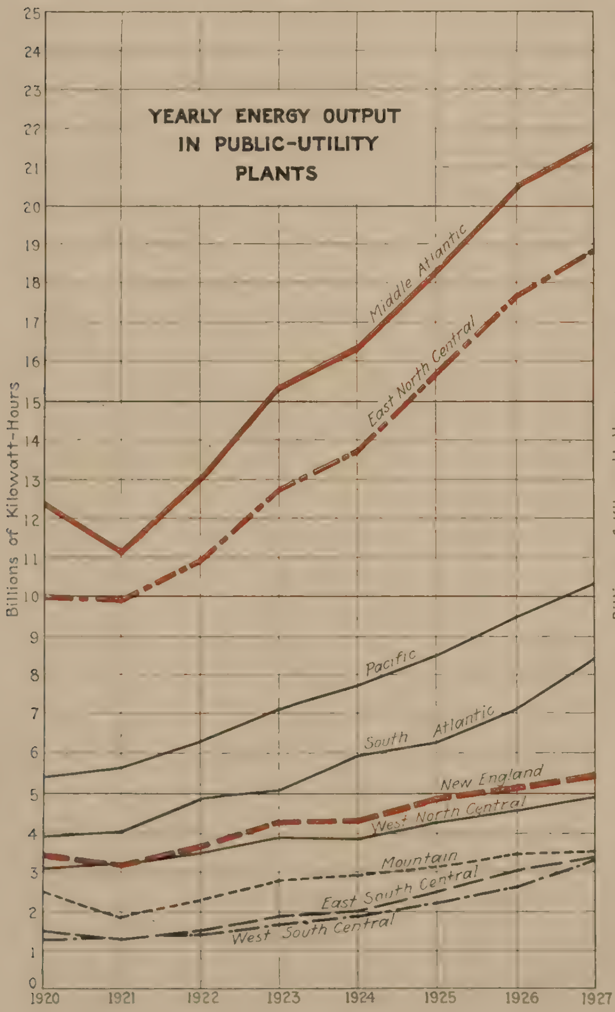
ELECTRICAL energy production is generally acknowledged to be a reliable indicator of industrial activity. Broadly speaking, those countries or regions which range high in this regard are conspicuous industrial regions; those in which the growth in energy output is relatively rapid are likely to be advancing at a corresponding rate industrially.

The accompanying curves of regional energy production in public utility plants of all kinds were plotted from statistics published by the United States Geological Survey. One is drawn to the ordinary uniform scale. It shows the three regions constituting the industrial belt along the northeastern portion of the country as comprising the great power-using section.

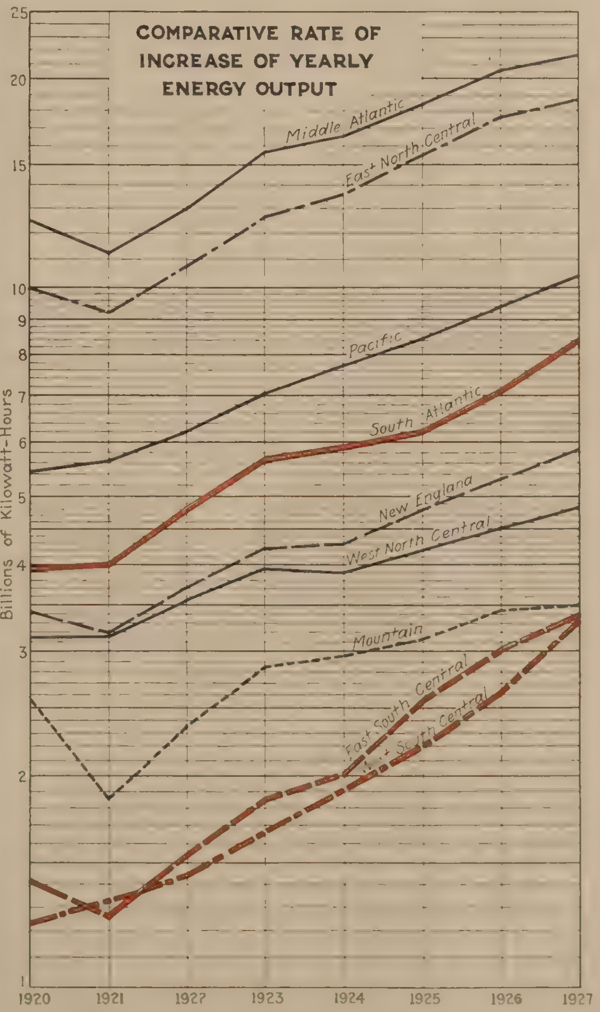
But the three Pacific States, with a smaller population than New England and about a quarter as populous as the Atlantic States, far exceeded these two regions in their relative use of electricity.

On the other chart the same figures are plotted, but to a scale that shows equal percentage growth by an equal slope of the curves, regardless of the actual amounts. The steepest slope indicates the fastest rate of increase.

A predominant position with respect to rate of growth is at once evident in the two South Central regions. The other Southern section, the South Atlantic, although much higher in absolute output, has had a slower rate of increase, but taken as a whole the South has been gaining in electrical output more rapidly than the rest of the country, with the Pacific States next in order.



*The industrial Northeast has the largest output*



*The "new South" has the most rapid growth*

# New England Production 2.7 per Cent Down During First Quarter

THE rate of general production in the New England States during the first quarter of 1928 was on an average about 2.7 per cent under that reported for the same period during 1927, as indicated by the consumption of electrical energy by some 400 large manufacturing plants scattered throughout the section. As has been the case during the last five years, the peak of operations in New England manufacturing plants as a whole this year was reached in February, the March rate of production, after correction is made for the number of working days, being about 6.2 per cent under February. The March activity was also 2.6 per cent under March, 1926.

The favorable position of New England industry as a whole, however, is evidenced by the fact that all of the primary industries with the exception of textiles reported an average rate of production during the first quarter materially above that reported for the same period last year. Textile plants as a whole have been reporting a lower rate of production than the year previous ever since last September, the low point being reached in December, when the rate of operations was 22 per cent under December, 1926. The high weight given to the index of textiles activity serves to bring the index of general activity below that of the year previous.

*Indexes of Productive Activity in the New England States*

All Figures Adjusted for Number of Working Days

| | March, 1928 | Feb., 1928 | March, 1927 | Average for First Quarter, 1928 | Average for First Quarter, 1927 |
|---|---|---|---|---|---|
| All industry | 112.3 | 119.7 | 115.2 | 113.7 | 116.8 |
| Chemical and allied products | 134.8 | 135.8 | 102.5 | 130.2 | 113.7 |
| Leather and its products | 100.6 | 108.4 | 93.5 | 101.7 | 96.1 |
| Lumber and its products | 110.7 | 115.4 | ..... | 107.4 | ..... |
| Metal industries group | 120.6 | 133.1 | 113.7 | 126.5 | 118.7 |
| Paper and pulp | 136.2 | 143.0 | 116.0 | 139.4 | 125.0 |
| Rubber and its products | 120.4 | 126.0 | 114.8 | 117.8 | 116.5 |
| Textiles | 107.3 | 114.2 | 120.0 | 108.5 | 119.5 |

## *Social Values in Industrial Decentralization*

THE day of the single large production plant in an industrial center has passed. Both economic and social values have forced industrial decentralization. In a sense this trend is a by-product of technical progress, for electric power and electric machines make decentralization possible. Power can be delivered to a factory at a cost which is about the same in any part of the country. This power has been so used in machines and control mechanisms that any kind of labor can readily operate an industry after a very short period of training. Efficiency in production has come to mean a comparatively small plant wherein a single competent production executive has full scope to exercise his talent by direct control and scrutiny of all operations. Marketing efficiency dictates the use of multiple-production plants in local market areas tied together by a national sales and manufacturing policy. All these economic values are recognized and are being put to work in American industry.

But the social values are of equal importance, as pointed out by George M. Verity in this issue. The trend toward decentralization makes for better working conditions and a more equitable distribution of wages to workers. A factory in a small town raises all standards of living. The farmer on the outskirts can diversify his farming and better his load factor; the worker can have his garden and can walk to work; the factory payroll increases the prosperity of the community, and thus all inhabitants get an increment increase in wealth and consequently an increment increase in standards of living. As Mr. Verity points out, industry has an obligation to the utilities to use their power, because this use makes possible the extension of electric service to farms and small communities. In the ultimate balance sheet the mechanization of civilization will give equal value to social and economic assets.

## *"Professionalizing" Public Relations Activities*

THIS is an age of extreme specialization and minute organization. The temptation to design complex mechanisms to attain results often within reach by simpler means is widely prevalent. It often assails those responsible for light and power company administration, for much of our modern thinking is based upon intricate systems of service. Little could be accomplished without proceeding from such a base, but mechanistic conceptions should not be followed slavishly. Public relations work, for example, is less a matter of machinery than of individual service and personal contact of employees and executives with customers and others. Good service at fair rates is basic, but, given this elementary requirement, the rest should follow without resorting to professionalized propaganda or building up a special organization to be the regular feature display of the company front window.

Organization for quiet, effective service within the company and the cultivation of friendly dealings with the public, yes; but no "ballyhooing" about "the fine department we have to build up good relations with customers" and no substitution of social welfare vernacular for simple business give and take. There should be no need of labeling the office doors of this department with anything but the names of those whose human understanding of their duties finds competent expression in their daily service in this important cause. Office machinery in its proper place, but in the long run the less the public thinks about the mechanism of corporate good will, the better. The ancient saying that Mark Hopkins on one end of a log and a student on the other created a university might well be paralleled by the statement that wherever a public utility employee and a customer meet on a plane of courtesy and fair intentions there is a public relations structure capable of being developed into an edifice of permanent worth and beauty.

* * * *

## *Resolutions Are Not Enough*

FOR a number of years the Natural Resources Production Department of the Chamber of Commerce of the United States has at the annual meeting of the chamber discussed natural resources with particular reference to electric public utilities. This year's meeting, held in Washington, again took up the subject, particularizing on group management and electric power and the investor, while the chairman of the department, M. S. Sloan of Brooklyn, stressed the water-power situation and legislation. The Natural Resources Production Department is, apparently, working hard, and yet, in spite of the airing of these vital public questions, business remains outwardly apathetic. Of what use are resolutions unless they are put in practice?

For example, the Chamber of Commerce of the United States is committed to the principle that government should not enter the realm of business to undertake that which can be successfully performed in the public interest by private enterprise. This principle it holds to be politically and economically sound. Nevertheless, the judgment of this organization, representing the collective business enterprise of the country, is apparently not regarded as of much weight by those who make the laws and those who administer them. Otherwise we should not have constantly thrust before us attempts to put the government into the electrochemical business, the fertilizer business, the coal business, the power business, the transportation business, etc. Would it not be proper at this time, considering the bent of Congress toward such legislation, for American industry to assert itself more vigorously on this question of government in business? We hold with the chamber that ruthless methods discredit all business and should not be tolerated. We believe that abuses should be checked and curbed in the public interest; but government ownership in any guise should not be sanctioned, however great the provocation. This, we feel sure, is the position of American business, and the Chamber of Commerce of the United States, without neglecting its other work, would render a great service to industry by arousing people to the danger which departure from this principle would bring upon the Republic and its institutions.

* * * *

## *Price Cutting— the Cause and Cure*

MANY men have been wrecked by living beyond their incomes. Many men live successfully within their incomes. The amount of the income has very little to do with it. It is a matter of principle, a practical matter of policy with a man whether or not he shall discipline himself and his household to the point where expenses shall be held within the family resources. It is, after all, a simple matter to understand, however hard it is to live up to the precept.

For all that men may say, it is precisely the same principle that is involved in price cutting. The only difference is that in business the sources and possibilities of the income and the character and diversity of the expenses are highly organized and much more complicated. But the control still lies in that same simple element of courage that enables men to pocket pride and face embarrassment and alter plans and win the loyal co-operation and support of the others who may be affected. In family life it entails the sacrifice of pleasure and comforts. In business life it entails the sacrifice of volume, the curtailment of production and sometimes the reduction of the organization. Either is hard to do and usually should not be done if by effort and ingenuity overhead costs can be cut or the income can be increased. Price cutting is like running up unpaid bills. It saves face temporarily and feeds false hope, but if carried too far leads to disaster.

At the present time American industry is volume-mad and electrical manufacturers have been afflicted with the epidemic. To get volume of sales too many of them are cutting prices and sacrificing profits in a struggle to maintain a condition of overproduction by striving to snatch the order away from the other fellow and keep the factory operating at full capacity. The trouble is that in industry it does not stop there. For cut prices lower market levels and demoralize values because other sellers feel obliged to cut, and soon profitless prices become established and are temporarily unescapable. And yet some manufacturers refuse to scramble for orders this way. They don't cut prices. If they cannot get business on a basis economically sound, they let somebody else take it. They reckon the prestige of their product to be worth more than their natural pride of volume. When they face a period of buyers' market they recognize that the only cure is limited production and they shoulder their responsibility. They live within their income.

Price cutting is primarily the false fruit of a state of mind. The seller indulges in it to save volume. The buyer sees in it an opportunity to save money. And in the end both lose.

## *Astral Analysis by Atomic Emissions*

IT IS known that the emission and absorption spectra of stars permit a chemical analysis of their constituents to be made. Not content with this knowledge, research workers have made recent advances in atomic physics and spectrum analysis that give promise of a knowledge of the physical conditions of the stars. Each star gives a continuous spectrum as well as absorption and emission line spectra, and these two facts are seized upon by research workers to find out whether these spectra come from solid, liquid or gaseous masses.

The method used in the application of atomic physics to the exploration of these stars consists in the correlation of the temperature and pressure of the fixed stars with definite excitation energies obtainable in laboratory experiments and, further, in the comparison of the spectra emitted in these laboratory experiments with those of the fixed stars. Results are not complete, but data are accumulating rapidly. These researches afford more proof of the basic nature of electricity and its importance as a research tool.

## *The New-Old Idea in Industrial Lighting*

IT WOULD be absurd to liken present practice in industrial lighting of the best types to that of twenty years ago, when the present illuminating engineering movement was fairly getting under way. But the pendulum swings in engineering practice as in other things, and at the present time we are at the beginning of a new swing which to a certain extent is back in the direction of the localized lighting so common in days past. This localized lighting, however, is so different from the old as hardly to be recognizable as having points of similarity. The old practice in factory lighting of hanging a lamp on a drop cord over each place where work was to be done, supplemented in some of the better factories with arc lamps to give a background of general lighting, has changed in the last twenty years to general lighting of high enough intensity to do away to a large extent with the necessity of localized lighting. The cheapness of light and the desirability of doing away with troublesome drop cords have been important factors in bringing about this change, as well as the increased productivity and cheerfulness and the avoidance of accidents that go with a system of adequate general lighting.

General lighting by uniformly spaced luminaires with spacings and mounting heights according to the commonly accepted rules of good practice is giving excellent results as compared with the old methods, but the intensity of illumination by the general lighting method must be sufficient to meet the most exacting requirements to be found anywhere in the entire area. Our knowledge of the lighting intensities necessary for the best and most rapid work has now progressed to a point where it becomes evident that for operations on dark materials, under some circumstances, intensities of 30 to 100 foot-candles are economically desirable and are being used instead of intensities of about one-tenth those values, which were previously considered very excellent general illumination.

The attention of designers is again naturally led to producing these relatively high intensities at the points where such high intensities are needed without the expense of producing them over the entire working area. It may be cheaper and more satisfactory to produce a fairly uniform intensity of 10 foot-candles, for example, over an entire working space than to resort to the complications and inconvenience of providing luminaires for localized lighting to get 10 foot-candles at certain designated working points, with the general level at other places much lower. With the cost of artificial light as it is at present, the possible savings in operating and wiring costs by the latter method may easily be offset by the interference with production. With ten times as much illumination required at certain critical working points it is easy to see that the answer to the problem may be different as the cost of light becomes larger in proportion to the labor factor of the production cost.

Along with this trend to localized lighting has very properly come a more careful study of what lighting conditions produce the best vision in specific cases. Mass production operations are now carried on upon a scale that justifies much thought and attention being directed to just how to produce the best visibility for the worker at any given step in a process, rather than simply "smearing around the foot-candles" promiscuously and trusting to luck that the job will be really well lighted. Dr. Percy W. Cobb of Nela Park has repeatedly urged this from the laboratory scientist's point of view in Illuminating Engineering Society papers the past three years, and the practical importance of such studies of quality in industrial illumination was most strikingly brought out by the paper on "Quality Industrial Lighting," written by Arthur A. Brainerd and abstracted in the ELECTRICAL WORLD of February 4. In this paper, which won the McGraw award at the N.E.L.A. convention last year, various examples are given where the quality of illumination as to uniformity and shadows and the contrasts of the objects being worked upon with the background were very important factors and where increase of illumination intensities without looking to these factors would give disappointing results. From which it is apparent that, although illumination design methods have been remarkably simplified and standardized in the past few years, there is still plenty ahead for the advanced lighting expert to do in the way of helping the manufacturer to get the conditions which are best for visibility in various processes.

* * * *

## *An Uncompleted Job*

IN A STATE that shall be nameless and in a year that does not matter an electric light and power company decided to build a hydro plant in a certain valley. It was a partly wooded, farming country and, being free from "hot-dog" stands and gasoline filling stations, was easy to look upon. The utility, being community-minded, designed a dam and power house that would be a creditable addition, if not an improvement, to the countryside. As is so often the custom, the highway, formerly at a lower level upstream, was diverted to cross the dam, and when the project was completed it brought many motorists to the property of the power company and its well-planned hydro-electric project. During the process of construction barracks were erected on either side of the valley directly adjacent to the dam, and since certain fine old oaks and pines stood in the way they were cut down. Natural sand pits were at hand, and great yellow gashes on the hillsides told of the removal of construction material. When the job was completed the barracks were torn down, and the engineers, by industrious figuring, announced a cost of $185 per kilowatt and congratulated one another upon the completion of so fine a job, economically done.

What was the cost of that station? Should it not have included the planting of small trees to take the place of those removed? Did it not properly require provision for the filling in of the cellars and foundation areas of the dismantled structures? Should the raw, telltale pits remain as mute evidence of an uncompleted task that a few hundred bushes would have soon brought to a conclusion? Less than one per cent increase in cost would have accomplished wonders in skilled hands. It is, assuredly, a passing day when thoughtless, unconscionably poor economics permit the establishment of a final cost which omits an adequate cleaning-up process. It is an unfortunate day for the utility that neglects a magnificent public relations opportunity that shrieks, not knocks, at its door.

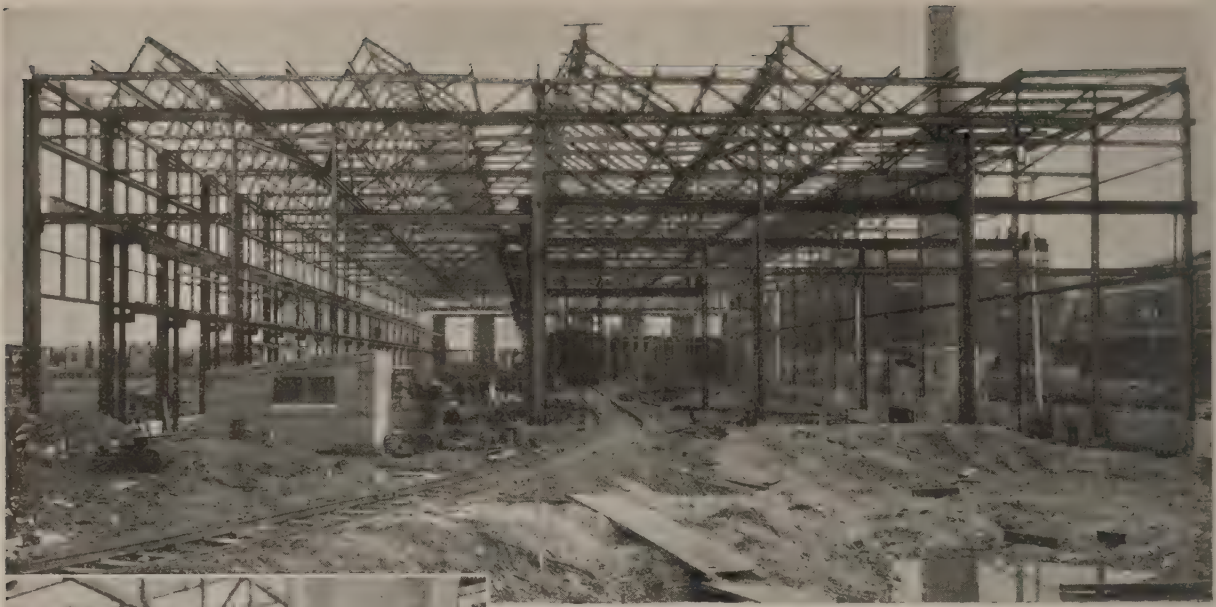
* * * *

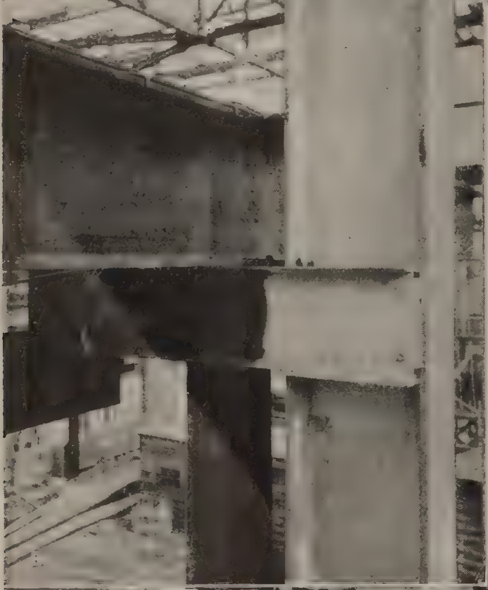
## *Modern Legerdemain*

THERE is always something fascinating about the sleight-of-hand performer and his amazing series of impossible tricks. Even the small boy, however, realizes that twenty pink rabbits cannot be contained simultaneously in the one silk hat from which they are apparently drawn, and that the bowl of goldfish has not vanished into the air when the mystic passes have been completed over the soft blue cloth. Why are some power-station engineers so ingenuously credulous about their ability to cause equally tangible materials to disappear without trace? It is apparent that the goldfish and the non-oxidizable content of the coal burned in pulverized-fuel plants have both disappeared from view, and it is equally certain that they still exist somewhere.

A steam generating station utilizing 500 tons of coal a day with a conservatively estimated ash content of 6 per cent has 30 tons of solid material to dispose of properly whether a stoker-fed boiler or pulverized-fuel equipment is used. Some of it will inevitably reach the open air; with stoker-fed furnaces this is relatively limited. It is amazing to hear engineers who have lived and worked through the era that has minimized the smoke nuisance state that they do not know where the ashes go and that there is an almost negligible quantity of which to dispose. The ashes, as any one on the leeside of the plant and possibly many miles away can tell you, are floating gently down on the countryside. Ten or twenty tons of impalpables per day constitute an amazing contribution to the community, however clean and sootless this powder deposit may be.

Official data of test runs in one pulverized-fuel installation where special precautions have been taken to control ash deposits indicate that while an average of 3.68 per cent of the dry coal is reclaimed as slag from the combustion chamber, the total flue refuse per pound of dry coal burned amounted to 0.0994 pound. Slowly indeed has industry learned that refuse is not disposed of when acids and dyes are poured into previously attractive streams, that smoke pollution of the air is a civic offense, in addition to being unprofitable, and that valleys were not made for refuse pits. The past points the way. Ashes must be disposed of, not blown into the air and forgotten by all but one's neighbors.





# *Arc-Welded Building*

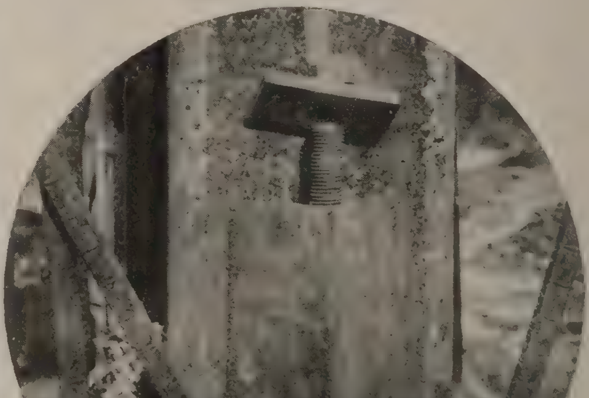
A SAVING of 125 tons of steel was made possible by arc welding the frame instead of riveting. A total of 989 tons of steel was used, of which 745 tons passed through the welding shop of the American Bridge Company at Trenton, N. J. The building is being erected by the U. G. I. Contracting Company of Philadelphia for the General Electric Company at its new plant at Philadelphia.

A—View from rear of building. It is joined by a transept to the existing building seen on the right.

B—Details of crane runway brackets. Bolts were used in some cases to hold the frame in place before welding.

C—Welding a crane column to its base.

D—Method of connecting column to anchor bolts, utilizing steel angle welded to column.



# Politics and the Colorado River

## Scheme to inject federal government into power business disguised as safeguard against Imperial Valley floods

By H. I. Harriman
*President New England Power Company, Boston, Mass.*

*H. I. Harriman*

UNDER the guise of a beneficent plan to protect the Imperial Valley of California against floods from the Colorado River by damming that stream at Boulder Canyon, developing hydro-electric power for transmission to the Los Angeles district and constructing a water supply from the Colorado Basin to serve a future population of 5,000,000 in southern California, it is proposed to launch the United States government into the power business at enormous cost and with all the uncertainties which beset vast political undertakings entered into without due regard to economic factors which should control action in such a situation.

A proper understanding of the problem of the Colorado River demands a brief explanation of the topography of its basin and the characteristics of its river flow. The Colorado Basin lies between the Continental Divide and the Coast Range. It includes southern Wyoming, parts of Utah and Colorado, the western half of New Mexico, substantially all of Arizona and slight areas in Nevada and California. Its area of more than 200,000 square miles is a territory larger than the German Empire and comprises about one-thirteenth of the entire area of the United States. It is a land of extreme variations in rainfall, in elevation and in the character of the country. The northerly part of the basin is highly mountainous and heavily timbered, a territory of warm summers and cold winters, a land of deep snowfall, a region that stores snows of winter and pours them forth in irresistible floods in the early summer.

The middle section of the Colorado Basin is a territory of low rainfall, six or seven inches; of high plateaus and of vast canyons. In no place in the world are there such deep, marvelously colored and wonderfully beautiful gorges and canyons.

The southern portion of the basin is a desert country, relatively low in elevation, with a rainfall varying from three to four inches, and of tremendous summer heat, 115 to 120 deg. being not unusual temperatures over much of this southern area in the months of June, July and August.

Irrigation is of tremendous importance in the arid West. The normal annual flow of the Colorado River is about 17,000,000 acre-feet, extreme years ranging from 9,000,000 to 25,000,000 acre-feet. Storage of water is vitally essential. The normal flow will irrigate about 5,000,000 acres, but in extremely dry years only half that area can be served. The Reclamation Service estimates that in the United States basin of the river about 7,000,000 acres could be irrigated if the water supply was sufficient. To this we must add about 1,000,000 acres in the delta region of Mexico. Already about 2,500,000 acres in the United States basin is irrigated, plus 200,000 in Mexico.

In 1921 representatives of the various states in the basin convened to draw a treaty which would definitely divide the waters of the river between the various states and permit the development of storage without fear that the states not benefited would be deprived of the future use of their just portion of the water.

The conference, while only partially successful, agreed that the four upper basin states should always so regulate their takings for irrigation that over a ten-year period an annual average of not less than 7,500,000 acre-feet should pass Lee's Ferry for use by the three lower basin states, and to this was added 1,000,000 acre-feet for the use of the lower basin states represented by the flow of the Gila River.

Unfortunately, the treaty did not attempt to divide the waters between the various states in the upper and lower basins, and so far Arizona has failed to ratify the treaty, fearing that without an agreement with California it would be unsafe for her (Arizona) to consent to a divi-

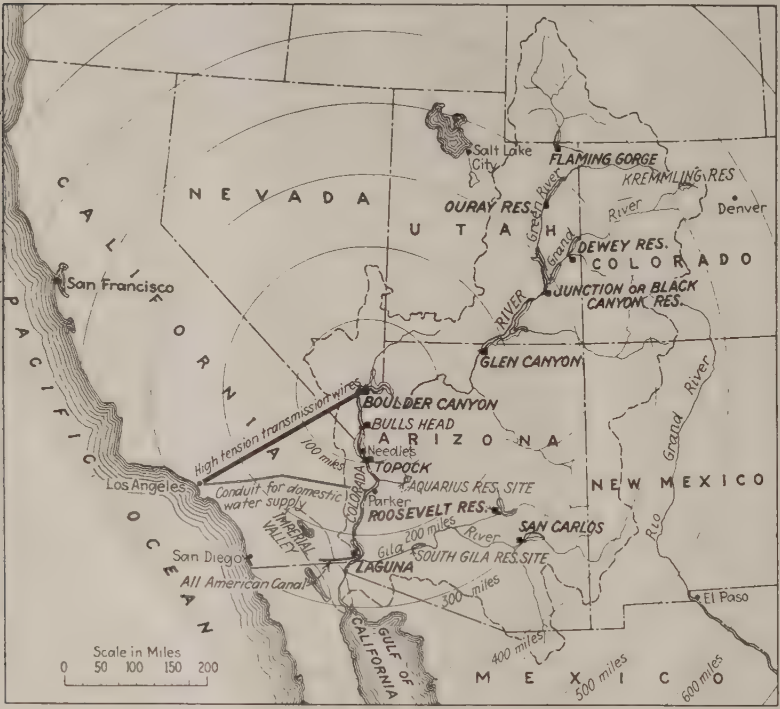
### Sound Expert Advice

*IMPRESSIVE because restrained and convincing because it offers a constructive program based on competent personal investigation on the ground, Mr. Harriman's analysis of the Boulder Dam project and the related political program for utilizing the Colorado River at the expense of the federal government deserves careful reading by every friend of individual initiative in the United States.*

*Mr. Harriman shows most effectively how protection against floods can be attained at a cost far below the anticipated outlay required to embark the federal government in the power business as a gigantic byproduct of an apparently innocent scheme to regulate and utilize stream flow in a basin occupying one-thirteenth of the area of the country.*

sion of the waters between the upper and the lower basins unless simultaneously a treaty were enacted between California and Arizona giving Arizona protection against the immediate appropriation by the Sunset State of more than her share of the flowage into the lower basin states. California's ratification is conditional only and is to be made effective if the United States creates a huge storage reservoir on the lower river.

The upper basin states demand ratification without reservations. The cost of placing water in the Imperial Valley of California is probably not over half the cost of delivery to the high table lands of Arizona, and until there is a division of the water to which the lower basin states are entitled Arizona will probably refuse to ratify the treaty. Both Arizona and the upper basin states fear that Mexico will put to prior use much of the water that otherwise might be used on United States land. Water is the lifeblood of these states and each state fears that Mexico or some other state will deprive it of a part of the water that it might otherwise use and doom a portion of its territory to perpetual desert.



*Colorado River basin center of political discussion*

In the canyon section of the river 6,000,000 hp. can be developed on a 60 per cent load factor. This exceeds the energy that can be developed on the St. Lawrence River or at Niagara Falls. Today there is little market for this potential power, as the territory is very sparsely settled with no industry and no local use. Only the lower section of the river lies within transmission distance of the large electrical market of southern California, but to any one who visualizes the phenomenal engineering and industrial progress of the last 50 years it is not difficult to imagine that the entire potential power of the stream may be used within the next half century.

The danger of a break of the river into the Imperial Valley is ever present and the homes of 60,000 people with a taxable value exceeding $100,000,000 will be in constant danger until the federal government takes adequate steps to open a new and proper channel for the sea. Storage on the main Colorado River would of course reduce the flood menace to this valley, but the threat of floods from the Gila will still exist and the valley will never be safe, storage or no storage, until a new and adequate channel is cut to the Gulf.

Competent engineers affirm that if the United States and Mexico execute a proper treaty a new channel can be cut at a cost not exceeding $5,000,000 substantially parallel to the original channel of the river, which will safely carry the floodwaters of the Colorado to the Gulf without menace to the Imperial Valley and without danger of undue silting.

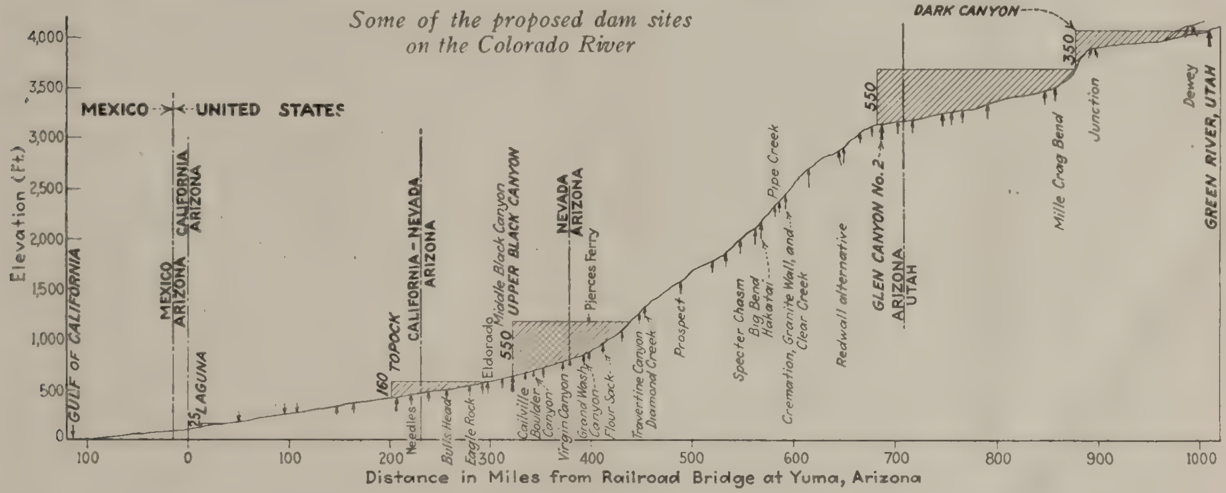
We turn now to consider measures pending in Congress for the construction by the federal government of a huge storage dam near Boulder Canyon, the creation of a 1,000,000-hp. plant and the digging of an all-American canal to turn the waters of the river into the Imperial Valley through a channel lying in the United States alone.

The Reclamation Service estimates the total cost of the above projects at $125,000,000. Others have estimated the cost at double that amount, but whatever the cost, it will be by all odds the largest business adventure within the boundaries of the United States which the federal government has ever attempted.

The merits and demerits of this proposed all-American canal involve a long story which will not be entered into here. Suffice it to say that a Board of Government Engineers has reported the canal to be feasible at a cost of approximately $31,000,000, but it also suggested that if the canal were to be built and a larger area of land watered storage would be necessary against the low water season.

The search for storage aroused the interest of Los Angeles. The managers of the municipal electric system there had for some time been perturbed over the necessity of buying from a private corporation a major portion of the electricity that it sold to its customers. The citizens were not, however, prepared to vote a huge bond issue that would enable the city to develop its own hydro-electric system and the suggestion of storage on the Colorado for the benefit of the Imperial Valley seemed to open the possibilities of federal aid. Astute politicians combined forces and one step has led to another until the early plan to irrigate a few thousand acres of mesa lands above the Imperial Valley has developed into a project to secure federal construction of an irrigation, storage and hydro-electric development of enormous proportions. This project is claimed to be the only sound method of protecting the Imperial Valley against floods, which have twice swept into it and which now threaten its existence.

It is universally conceded that the federal government should take adequate steps to protect the Imperial Valley from another disastrous flood. The valley is menaced, not primarily because of the size of the Colorado flood, but because the original stream bed of the river became clogged during the two years or thereabouts when it flowed into the valley. Recently American engineers, in consultation with Señor Mejorada, a distinguished Mexican engineer, have revived and improved the plan for an adequate channel protected by levees from the international border to the Gulf and they estimate its present cost at $5,000,000. If this plan is carried through the Imperial Valley will be adequately protected against all floods and a channel provided which will maintain itself by natural erosion and with little, if any, annual cost. It is a plan approved by Mexico and undoubtedly the United States government can secure the right for the construction and maintenance of this channel if proper representations are made at Mexico City. Yet we hear nothing of this project, though it is the least expensive and most adequate plan for protecting the Imperial Valley against floods.



*Some of the proposed dam sites on the Colorado River*

This channel is needed whether or not storage is constructed on the main Colorado River, for the Gila River and other streams entering below the proposed site of the Boulder Canyon dam produce short floods of as great height, but of less duration, as those of the main river. The Boulder Canyon project would in no way protect the Imperial Valley from the Gila River floods.

The most available site for storage is probably the Mojave Canyon site below Needles, sometimes known as the Topock site, where a dam of moderate height will impound 10,000,000 acre-feet at a cost estimated between $10,000,000 and $15,000,000. This project was seriously recommended some year ago by Secretaries Weeks, Works and Wallace, who then comprised the Federal Power Board. It did not meet with favor in southern California because it did not include a great power development or an all-American canal.

Storage should, of course, be created in the upper stretches of the river above its rapid drop so that the flow may be regulated and conserved for all the potential power plants of the stream. In the upper basin there are two or three sites at which large storage can be created, and on the main river there are three additional sites. Of these last, at the upper site, Lee's Ferry, where 20,000,000 acre-feet can be stored and the river regulated to an even flow of about 15,000 second-feet, the most desirable location appears to exist for a great storage reservoir. This is at the head of the canyon section of the main river and would make possible the development of the entire stream for power. A second site is at Boulder Canyon, or Black Canyon, where a storage of equal size can be created, and finally there is the Topock site below Needles, in the Mojave Canyon, where a reservoir of any size up to 20,000,000 acre-feet can be created. A storage of 6,000,000 acre-feet is more than sufficient to prevent destructive floods on the lower river.

With the floods of the main river regulated by a reservoir at Lee's Ferry the construction problem of all the lower dam sites on the river will be greatly simplified. Preliminary borings indicate rock of a suitable character, but much further detailed study should be given to this site before any work is started.

A dam at Boulder or Black Canyon, near the foot of the rapid water of the Colorado River, is also probably feasible, although the bedrock is so far below the water level as to make the problem of building the foundation under a torrent rushing through a box canyon quite unprecedented and some engineers say all but impossible.

The storage capacity of Boulder Canyon will be of value in regulating the stream for any power plant located at that dam, or for further irrigation in the Imperial Valley and in Mexico, but it will have no value for the great power plants which will eventually utilize the main power of the river. At some time in the future storage must be created either at Lee's Ferry or in the upper basin to regulate the flow of the Colorado for the thirteen or fourteen power plants which will ultimately be built to utilize the fall in the Grand Canyon. When this upper storage is created the storage at Boulder Canyon will be unnecessary and the Boulder Dam will become a power dam without other function.

At the Topock site a storage of from 6,000,000 to 10,000,000 acre-feet can be created at a cost of from $10,000,000 to $15,000,000, or a storage up to 24,000,000 acre-feet at a corresponding additional cost. A 6,000,000 acre-foot storage will be of ample size to reduce the floods on the main river to a point that will in no way threaten Imperial Valley and substantially to increase the low water flow of the Colorado during the irrigation season, but no great amount of power can be developed at Topock. For this reason this project has not appealed to the managers of the municipal plant of Los Angeles, who desire to have the federal government supply them with electrical energy, or to the promoters in the Imperial Valley who wish to have the carrying charges of the all-American canal met from the sale of power.

The Boulder Canyon project is a power project pure and simple and is an effort to inject the federal government into the business of generating electricity. Boulder Canyon is not the proper location for a storage dam for the regulation of the main river. A river should be regulated at the head of its rapids and not at the foot. Again, the Boulder Dam is entirely unnecessary for the protection of or for irrigation in the Imperial Valley because both of these objects can be attained at a small fraction of the cost of the Boulder Dam by the construction of a dam at Topock.

### Boulder Dam in Its True Light

Let us examine the Boulder project in its true light as a project to force the federal government into an investment of not less than $125,000,000 for the purpose of generating power for the cities of southern California and for the further purpose of building an all-American canal which the Imperial Valley cannot afford to carry.

If the project is carried out there will be developed at Boulder approximately 1,000,000 hp., or 750,000 kw., on a 55 per cent load factor. This means the annual production of about 3,500,000,000 kw.-hr.

The Federal Power Commission, which has carefully examined the market for Boulder energy, estimates that it will take southern California from nine to ten years to absorb this block of power after delivery is begun. It further estimates that the cost of Boulder power delivered at Los Angeles, including all transmission costs and losses, will be between 4¾ and 5 mills per kilowatt-hour. This is on the assumption that the Boulder project, including the all-American canal, will cost not exceeding $125,000,000. If the cost of the project should exceed that amount the cost of energy delivered in southern California would be increased proportionately.

### Steam Power Costs Decreasing

The cost of power from Boulder Dam in fairness should be compared to the cost of power generated in a modern steam plant near Los Angeles. The Southern California Edison Company is now producing power, all charges included, in its Long Beach plant at slightly less than 4½ mills per kilowatt-hour. In its new and improved plant now under construction it is expected that the cost will be reduced to 3⅞ mills per kilowatt-hour, and in view of the remarkable strides that are being made in increasing the efficiency of steam plants it is not fanciful to imagine that the cost of steam power in southern California, with oil at its present price, will be approximately 3 mills at the time when the Boulder Dam project can be completed. Even if the oil supply of southern California is exhausted and it is necessary to turn to Utah coal, energy cost should not exceed 4 mills per kilowatt-hour. Thus the power users of southern California will be paying a mill a kilowatt more for Boulder energy, with the uncertainties of long-distance transmission, than for steam energy generated at their door. This will mean an annual loss of $3,500,000 and it may be twice that amount.

Boulder power at 4¾ mills is based upon the assumption that the dam itself can be built for $40,000,000, yet it must be recognized that the project is one of great hazard, that a dam 550 ft. high has never as yet been constructed, that it is necessary to go 127 ft. below the channel of the river in order to find bedrock and to excavate perhaps 20 or 30 ft. into this bedrock, thus making the total height of the dam from bedrock to crest nearly 700 ft., and that the work of clearing and preparing the foundations must be done in a stream less than 300 ft. wide and carrying each year floods of half the volume of the water which passes over Niagara Falls, and in some years a flow equal to the flow of Niagara. Competent engineeers have estimated the cost of the Boulder Dam at from $90,000,000 to $100,000,000 and some say that the project is almost impossible of accomplishment because of the unsurpassed difficulties in building such a huge dam in such a narrow gorge carrying such enormous floods.

It is urged that stored water from the Colorado River is necessary in order that Los Angeles and the other cities of southern California may have adequate domestic water supply. Los Angeles now gets its water supply from local sources and from the Owens River, and the best engineering evidence would indicate that this supply can be doubled before it is necessary to turn to the Colorado. Obviously the water of the Colorado should not be used by Los Angeles until every other source has been exhausted because of the great distance which it must be carried and the fact that it must be pumped over a ridge of the coast range 1,500 ft. high. When the population of Los Angeles reaches 5,000,000 it may be necessary for her to secure a part of her water supply from the Colorado, but even Western optimism must admit that such a contingency will not arise for several decades.

It is further urged that the Boulder project is required in order to protect the Imperial Valley from floods, yet we have seen that this protection can be supplied in other ways at a fraction of the cost.

Again, it is stated that Boulder power is required by southern California. While admitting the great growth of the power demand of the Sunset State, we have seen that its power requirements can be furnished at a very much lower cost from steam.

Finally, the need of additional stored water for irrigation is stressed. Such additional supply can be had at moderate cost from the Topock Dam, and further engineering study will reveal where the main storage of the Colorado should be located.

### A Sane Program

What, then, is a sane program for the development of the Colorado River? The one pressing need is the protection of the Imperial Valley from floods. This protection can best be supplied by the construction of a suitable channel from the international border to the Gulf of California, and it is suggested that the first step should be the negotiation of a treaty with Mexico providing for the construction of such a channel.

As a second step the Topock Dam should be constructed both for flood protection and for irrigation. The construction of this dam requires no treaty with Mexico and work on it can be started at once.

The new channel and the Topock Dam can together be constructed at a cost of from $15,000,000 to $20,000,000 and together they will protect the Imperial Valley from floods and they will furnish it with such additional irrigation supply as may be required in the next decade.

With these two projects under way the Engineering Corps of the United States Army, assisted, possibly, by other engineering departments of the government, should be given an adequate appropriation with which to make a complete study of the entire river. Such a study should include borings at all possible dam sites, complete surveys and a comprehensive plan which will most efficiently provide for the future development of power and irrigation. Such a program is sane, constructive and relatively inexpensive and will avoid costly mistakes and a wasteful use of one of the greatest resources of the far West.

## System Frequency Control

By C. P. Hubbard
*Chief System Operator Detroit Edison Company, Detroit, Mich.*

FREQUENCY regulation of the Detroit Edison system is controlled by the largest power house under orders from the load dispatcher. The ratio of system capacity held in reserve for regulating purposes to capacity in actual use is about one to eight. That is to say, the amount of idle capacity floating on the line and available for regulation is approximately one-eighth of the total load. Each power house carries a definite percentage of the total system load. This figure is given by the load dispatcher each half hour, or, in case of sudden load changes, every fifteen minutes. If the regulating power house should be subjected to a sudden rise in load between normal load instructions the switchboard operator in the power house informs the load dispatcher and a new allocation of the total load is made. In a case of this kind the controlling power house continues to regulate at the rise in load until the new allocation is made by the load dispatcher.

In order to restore system frequency to normal after emergency, such as switch trip-outs or loss of generators, the proportionate parts of the system load are put on reserve capacity, which is always available at all power houses. Reserve capacity is never allowed to get below a point at which the largest generator in the system might be lost and the frequency still maintained. Under certain emergency conditions the controlling power house relinquishes frequency control and it devolves upon one or more of the other power plants. Such an emergency would be a separation of the various system units by which a unit which may be in trouble is dropped out and the others continue to function as independent elements. In cases of extreme trouble a lower limit of 54 cycles has been set as the frequency at which a beginning should be made in dropping customers off the system in order to lighten the load.

In the control center, which is the system operator's office, a Westinghouse centrifugal recorder, type RF, is the master frequency control of the entire system. This meter gives a very accurate record of frequency variation on account of its sensitivity and the width and rate of travel of the chart. The company does not sell telechron or synchronous clocks to its customers, but these are used in the stations and power houses and on various types of demand meters on customers' premises. The master clock is corrected once each day by raising or lowering the system frequency very slightly. Adjustment is seldom necessary as the frequency is held practically constant. The Detroit Edison Company has at this time only one major interconnection, with the Consumers Power Company, made early in 1928. The Detroit company regulates the frequency of both systems.

## Unique Bridge for Locating Cable Faults

By Charles H. Smith
*Department of Standardizing and Testing*
*Edison Electric Illuminating Company of Boston*

THE Boston Edison Company has recently installed at its Edgar station a specially designed apparatus for locating cable faults by bridging. The outfit is composed principally of two main units, a very sensitive bridge with separately mounted galvanometer and an auxiliary motor-generator set for supplying direct current at 1,500 volts. For low-resistance faults a 125-volt direct-current source, provided with a series rheostat for current control, is used instead of the 1,500-volt source. The bridge and other parts of the equipment are insulated for 1,500 volts.

*Panel-mounted bridge and accessories for locating cable faults*

The bridge proper was furnished by the Rawson Electrical Instrument Company, Cambridge, Mass. It consists of a helically wound slide wire approximately 30 ft. long shrunk upon a bakelite drum. The operating lever makes ten complete revolutions as the slide moves from one end of the wire to the other, each revolution being indicated by a second arm geared to the operating lever. As the scale is divided into 1,000 divisions, each division represents one ten-thousandth of the cable length. As the length of the longest cable line from Edgar station is about 57,000 ft., each division represents not more than 11.5 ft. of cable.

In order to test the sensitivity of the bridge, a test was made on a line approximately 58,000 ft. long, with an artificial fault introduced at 10,000 ft. With a solid fault and 2 amp. flowing through the bridge a galvanometer deflection of one division represented less than 1 ft. of cable. With a fault of 1,500 ohms and only 0.075 amp. flowing a deflection of one division represented 10 ft. of cable. Thus it can be seen that very accurate bridging is possible with this type of bridge.

*Power bridge simplifies locating of cable faults*

Its chief advantage over other bridges, however, lies in the fact that by the use of the 1,500-volt generator, even on very high resistance faults (i.e., faults of 100,000 ohms or more), the current can be brought into the range of the bridge. For example, at the time of the above tests, it was found that a fault as high as 500,000 ohms could be located within one cable section by the use of the 1,500-volt sources. This is a very great advantage when a joint blows open under water, resulting in a high-resistance water fault. Use of the bridge enables a troubleman to go to the approximate location and by inspection of a very few manholes locate the blown joint.

Another unusual feature in this installation lies in the fact that the connections are all made to the cable through a permanent test bus. The leads from the bridge terminals and from the ground, where one is needed as in the case of a phase-to-phase fault, are all rubber-insulated leads attached to long wooden operating rods. These have clamps which can be attached, from the floor below, to the bare test bus in the ceiling of the test room. Then by means of a gang-operated switch in the switch mechanism room the cable is connected to the test bus and when jumpers have been properly connected at the far end the cable is ready for bridging. At the Edgar station end it is not necessary for the operator to handle loose leads in the cable terminal room at all, which makes the operation of the test apparatus unusually safe.

The front view of the control panels shows the bridge dial on one panel and with it the galvanometer and low-voltage current control. On the other panel is the control equipment for the 1,500-volt motor-generator, with a double range ammeter (1 — 10 amp.) and a 1,500-volt voltmeter, both with protective cases. The bridge slider is inclosed in a dustproof case. The scheme of connections is shown in the accompanying diagram.

## *Performance of Coal Pulverizing Equipment*

For Year Nov. 1, 1926, to Nov. 1, 1927

New Orleans Public Service Company, Inc.

| | |
|---|---|
| **9-Ton Fuller Mills:** | |
| Total coal pulverized, tons | 92,620 |
| Total hours operation, hours | 12,840 |
| Average coal pulverized per set of balls (4), tons | 14,250 |
| Average coal discharged per set of exhaust fan blades, tons | 23,150 |
| Average coal pulverized per set of pushers (4), tons | 28,500 |
| Average coal pulverized per spider, tons | 30,870 |
| Average coal pulverized per ball race, tons | 46,310 |
| **2½-Ton Fuller Mills:** | |

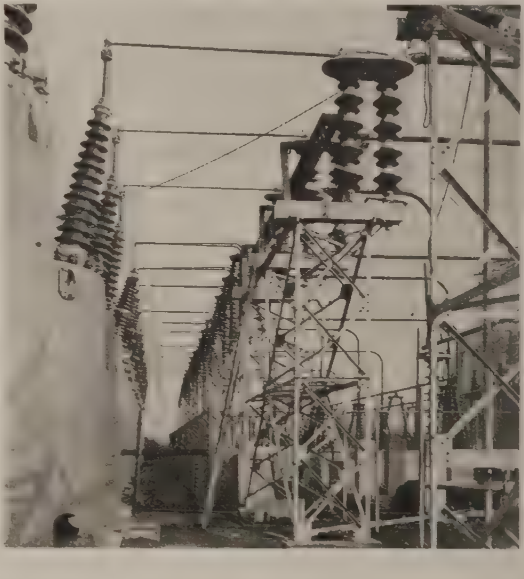
## Disconnecting Switch Contacts on Breaker Terminals



OWING to space limitations adjacent to the oil circuit breakers on the 220-kv. lines that link the Laguna Bell substation with the Long Beach steam plant of the Southern California Edison Company the disconnecting switches are mounted directly on the oil circuit breakers, as shown in the accompanying illustration. Six three-pole manually operated switches are used at this substation. The circuit breaker bushing serves as the third insulator column of a single-pole switch and supports the jaw contact. The disconnecting switches are type TTR "Hi-Pressure" units manufactured by the Railway & Industrial Engineering Company, Greensburg, Pa.

# Power from Pumped Water*

Water pumped to reservoir for later use in hydro plants. Rocky River development of the Connecticut Light & Power Company. River regulation controlled.

By E. J. Amberg
*Research Engineer Connecticut Light & Power Company*

THE Rocky River hydro-electric development of the Connecticut Light & Power Company has created considerable interest among technical as well as non-technical men as a project for regulating the flow of the Housatonic River below New Milford, Conn. Briefly, the development consists of a storage reservoir created on Rocky River, a tributary of the Housatonic, with a power and pumping plant on the Housatonic River, the power and pumping plant being connected by a single penstock with the reservoir.

The Rocky River basin is located north of Danbury and west of the Housatonic River and the site of the development is approximately 1½ miles by state highway from the nearest railroad station at New Milford. The basin has a drainage area of approximately 40 square miles, 8¼ miles of which is covered by the storage lake. The unusual features of this development lie in the fact that the drainage area of the reservoir basin will supply only about 1.5 billion cubic-feet of water in an average year, while the useful capacity of the reservoir is 5.9 billion cubic-feet. All water above the natural run-off required to fill the reservoir must be pumped from the Housatonic River against a head varying from 200 to 230 ft. While considerable excess hydro energy will be available for pumping, the studies and investigations for this development are all based on using secondary steam-generated electrical energy for pumping to be supplied over transmission lines from the Devon station of the Connecticut Light & Power Company.

### Acts as a Battery

The Rocky River reservoir may be likened to a large storage battery. Charging the battery is accomplished by secondary steam energy driving two electrically operated 8,100-hp. centrifugal pumps, delivering water to the reservoir. The battery is discharged by means of the 30,000-kva. generating unit at Rocky River delivering primary hydro energy. The efficiency of this storage battery for changing secondary steam energy into primary hydro energy is 61 per cent; this includes all losses from the 66,000-volt bus at the Devon steam station

through the pumping units into the reservoir and back through the generating unit to the 66,000-volt Rocky River bus. In other words, for every 100 kw.-hr. supplied by the Devon steam station in filling the reservoir 61 kw.-hr. is delivered by the Rocky River generating unit when the water is drawn out again. We must not, however, overlook the fact that below the Rocky River plant there is an additional total average head of 191 ft. available, of which 71 ft. is efficiently developed at Stevenson. If the head at Stevenson is added, then for every 100 kw.-hr. of steam energy 79 kw.-hr. of hydro energy is returned. If the total head from Rocky River to tidewater is added, 111 kw.-hr. of hydro energy could be obtained from every 100 kw.-hr. of steam energy used in pumping.

The Housatonic River had no means of regulation and the stream flow shows very wide variations. The only period of the year when any reliance can be placed on the river flow is in the spring. With the river plants at Stevenson and Bulls Bridge operated in conjunction with the Rocky River storage plant the 24-hour firm power of the hydro system is 11,000 kw. The chart (Fig. 3) shows the unregulated power duration curves for a typical dry, wet and average year, limited by the installed capacities of the Stevenson and Bulls Bridge stations, which together total 26,000 kw. The regulated 24-hour firm power of 11,000 kw. obtained by the addition of Rocky River is also shown. The respective areas between the 11,000 kw. regulated firm power and the power duration curves represent the energy which has to be furnished from storage. The amount required in each year varies considerably, being 9,500,000 kw.-hr. in the wet year and 39,900,000 kw.-hr. in the dry year. Of these amounts, 78 per cent is produced by the Rocky River station and the balance at Stevenson, generated from the water released from the Rocky River station. By applying the 24-hour firm power of 11,000 kw. to the upper half of the load curve, as shown in Fig. 4, curve 1, the total installed hydro capacity of 50,000 kw. can be used as firm capacity. Before regulation by Rocky River the combined firm capacity of the Stevenson and Bulls Bridge stations was only 10,000 kw., although the installed capacity was 26,000 kw. Therefore, by installing a 24,000-kw. generating unit in the Rocky River station and by regulating the river the firm hydro capacity has been increased by 40,000 kw.

To obtain the maximum benefits from such a storage development it is necessary to apply it to that part of the load requiring the smallest number of kilowatt-hours. When plotting system loads in the form of an annual duration load curve we will find that there is a decided peak. The reasons for this pronounced peak on the duration load curves vary; on systems like the Connecticut company, where there are no short time peaks of any extent, the seasonal changes in load are responsible. What appears as a very short time peak on the duration load

*To the left are the concrete intake tower, the surge tank and penstock to power house below.*

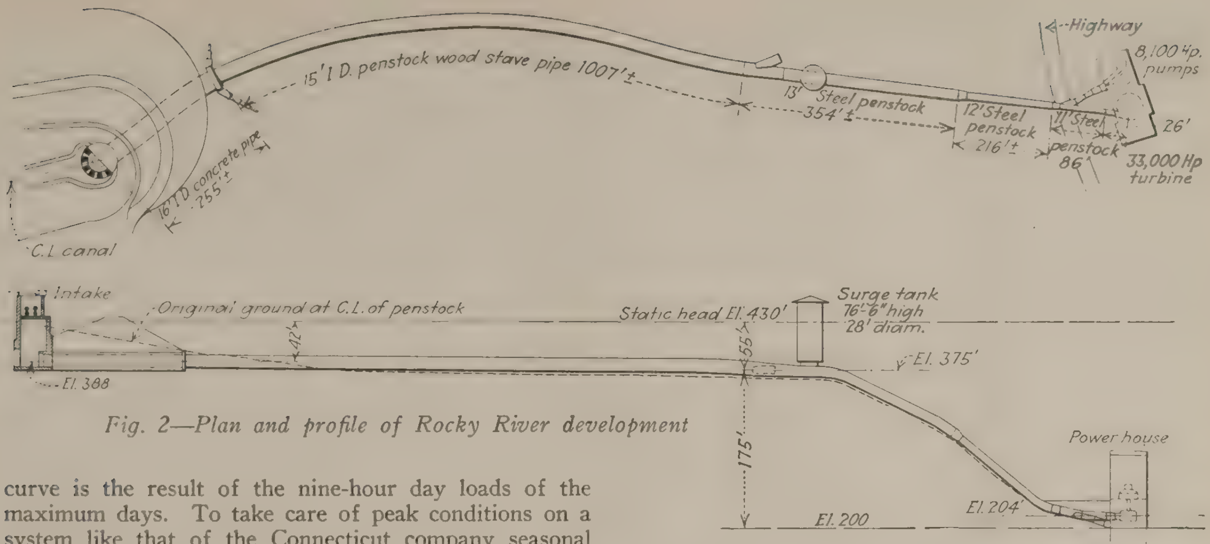

*Fig. 2—Plan and profile of Rocky River development*

curve is the result of the nine-hour day loads of the maximum days. To take care of peak conditions on a system like that of the Connecticut company seasonal storage in addition to weekly pondage is required. This seasonal storage is being provided by the construction of the Rocky River storage reservoir.

Two annual duration load curves are shown in Fig. 4; curve 1 represents the present approximate combined load of the Connecticut Light & Power Company and associated companies, while curve 2 shows the expected combined load for the year 1931. The upper half of load curve 1, and load curve 2 for that matter, contains only 18.2 per cent of the total kilowatt-hours; the load factor of this part of the load is 17.2 per cent. The advantage of applying the hydro generating capacity to the peak of the load and the steam generating capacity to the base of the load is quite evident from a study of this load curve. Assuming that the total load has increased 50 per cent, as indicated by curve 2 on Fig. 4, the same number of hydro kilowatt-hours represented by area *A2* would permit a firm hydro capacity of 65,000 kw., as against 50,000 kw. firm capacity of curve 1, or 15,000 kw. firm capacity could be installed without increasing the storage facilities. Additional capacity can often be installed at a low cost per kilowatt in existing plants, thus lowering the average unit cost per kilowatt of hydro capacity. Such storage development as Rocky River has, therefore, some inherent values which can be increasingly realized as the load increases.

Aside from the features discussed above, hydro plants have another great advantage in that they provide standby capacity which can be made available in a fraction of the time required at a steam station, because to get up steam and warm up a turbine requires time unless boilers are kept in service and excess turbine capacity is kept on the line to take care of sudden load demands. With the means of regulating the stream flow below Rocky River, it will be possible to develop the full head on this section of the river, which will then produce a total 24-hour firm power of approximately 23,000 kw.

The hydro capacity will again be applied to the upper half of the load curve, which from curve 1 on Fig. 4 shows a load factor of 17.2 per cent. In order to take care of possible changes in the load curve we will make an arbitrary increase in the load factor of one-third, which will change this load factor to 23 per cent. With a 23 per cent load factor and a 24-hour firm power of 23,000 kw. it will be possible to increase the total installed

*This dam diverts water into canal running to left and thence to intake tower* hydro capacity to 100,000 kw. by developing the full head of the river between tidewater and Rocky River.

The second 24,000-kw. unit at Rocky River is in addition to the 100,000 kw. capacity above referred to; its main function will be to act as a spare unit, which can be made instantly available. The second unit can be installed at a low unit cost, including the raising of the reservoir level, which will add approximately 1,000,000,000 cu.ft. to the useful storage capacity.

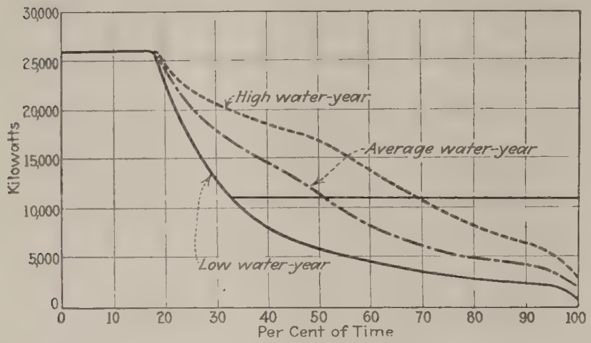

*Fig. 3—Power duration curves for combined output of Bulls Bridge and Stevenson*

The horizontal line on the chart represents Rocky River firm power

UNREGULATED

| | Square Miles | Head, Ft. | Kw. Per Sq. Ft. | Installed Capacity Kw. |
|---|---|---|---|---|
| Bulls Bridge | 782 | 104 | 6.27 | 7,200 |
| Stevenson | 1,510 | 71 | 4.40 | 18,700 |
| | | | | 26,000 |
| Rocky River | 35 | 214.2 | | 24,000 |
| Power | | | 15.55 | |
| Pumping | | | 25.35 | |

REGULATED BY ROCKY RIVER TO PRODUCE 11,000 KW. FIRM POWER

| | Low Water, Kw.-Hr. | High Water, Kw.-Hr. | Average Water, Kw.-Hr. |
|---|---|---|---|
| Rocky River output | 31,100,000 | 7,400,000 | 17,400,000 |
| *Stevenson | 8,800,000 | 2,100,000 | 4,900,000 |
| Total | 39,900,000 | 9,500,000 | 22,300,000 |

*Generated at Stevenson on water from Rocky River.

From the foregoing it can be seen that the Rocky River development has a considerable increased future value, by making it possible to develop the full head below Rocky River as the load of the system of the Connecticut Light & Power Company and associated companies increases. Without Rocky River further economic development of the river would have been impossible.

### Use of Water Illustrated

In concluding the first part of this paper an account of water utilization at Rocky River and Stevenson stations for a typical average year seems in order.

As stated before, with a full reservoir the water level will be at an elevation of 430 ft. The normal allowable draw-down is 30 ft., or to water level elevation at 400 ft. In this 30 ft. of draw-down, 5.9 billion cubic feet of water is taken from the reservoir. This amount of water in going through the Rocky River generator will produce 24,200,000 kw.-hr.

From the power-duration curve for an average year in Fig. 3 it will be seen that 22,300,000 kw.-hr. must be generated by water from Rocky River to maintain the 24-hour firm power of 11,000 kw. Of the total of 22,300,000 kw.-hr. the Rocky River station will furnish 17,400,000 kw.-hr., while the remaining 4,900,000 kw.-hr. is generated at the Stevenson station by the water discharged from Rocky River station. The amount of water that must be taken from the reservoir in order to produce 17,400,000 kw.-hr. at Rocky River station is approximately 4,030,000,000 cu.ft., based on an average figure of 15.55 kw. per second-foot.

The water used for refilling the reservoir falls into two classes, with two subdivisions in each class:

1. Run-off water from the Rocky River drainage area:
   (a) Water held back at a time when it would have spilled over the Stevenson dam.
   (b) Water held back at a time when it could have been used at the Stevenson station.
2. Water taken from the Housatonic River and pumped into the reservoir:
   (a) Water taken from the Housatonic River at a time when this water would have spilled over the dam at Stevenson.
   (b) Water taken from the river at a time when this water could have been used at the Stevenson station.

The following is a brief summary of the amount of water obtained from each subdivision for an average year:

1. The run-off from the Rocky River drainage area in an average year based on a net area of 35 square miles is 1.6 billion cubic-feet.

(a) The daily discharge records for the average year show that there are 58 days of the year when the flow of the river equals or exceeds 2.86 cu.ft. per second per square mile, the flow necessary to produce 24-hour full load at Stevenson. The run-off during the 58 days amounts to 0.84 billion cubic feet. This amount of water, when finally released from the reservoir, will utilize the additional head at Rocky River as well as at Stevenson.

(b) The difference, or 1.6 — 0.84 = 0.76 billion cubic-feet, is Rocky River run-off that is caught in the reservoir at a time when the river flow was less than 2.86 cu.ft. per second per square mile. This amount of water, when finally released, will utilize the additional head of the Rocky River station only.

2. The total amount of water to be pumped in an average year is 4.03 — 1.6 = 2.43 billion cubic-feet. The possible number of pump hours per week with two pumping units available is 336 hours. Load conditions, however, will normally limit the actual pump hours per week to 200 hours, which corresponds to an average pumping rate of 298 cu.ft. per second, as against the maximum possible rate of 500 cu.ft. per second, which is the capacity of the two pumps.

(a) The daily discharge records for the average year show that there are 58 days of the year when the flow of the river equals or exceeds 2.86 cu.ft. per second per square mile, the flow necessary to produce 24-hour full load at Stevenson, and 45 days when the river flow equals or exceeds 3.16 cu.ft. per second per square mile, the flow necessary to produce 24-hour full load at Stevenson after an average of 298 cu.ft. of water per second has been taken from the river at the Rocky River station. The amount of water pumped during this period is 1.32 billion cubic feet. This water when released from the reservoir will utilize the additional head at the Rocky River and Stevenson stations.

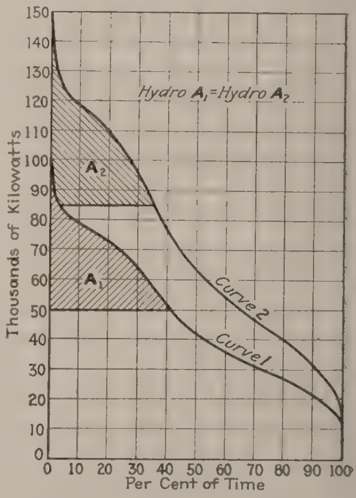

*Fig. 4—Present and 1931 Rocky River load duration curves*

| | Curve 1 | Curve 2 |
|---|---|---|
| Maximum hours, kilowatts | 100,000 | 150,000 |
| Load factor, per cent | 47.3 | 47.3 |
| Hydro, kilowatts | 50,000 | 65,000 |
| Increase | ........ | 15,000 |
| Hydro load factor, per cent | 17.2 | 13.2 |

(b) To fill the reservoir completely an additional amount of 2.430 — 1.325 = 1.105 billion cubic-feet of water must be pumped at a time when the river flow is less than 2.86 cu.ft. per second per square mile. This water when released from the reservoir will utilize the additional head of the Rocky River station only.

The storage reservoir or lake is about 10 miles long and 1¾ miles across at the widest part. It has a surface area of 8⅓ square miles and a shore line of approximately 60 miles. The main dam is located across Rocky River at a point about 1 mile above its junction with the Housatonic River. It is an earth-filled dam with a core wall. The lower part of this core wall consists of a 2-ft. concrete section which extends on the average 10 ft. above and an average of 5 ft. below the ground surface. On top of this concrete section was placed a 6-in. Wakefield core wall (timber) reaching up to an elevation of 435 ft. On the west end the concrete core wall was located in solid rock. This rock, however, dropped off rapidly below the surface at the location of the old river bed; from this point the core wall continued in earth. The material for the dam was obtained from the canal excavation and was placed in the dam by sluicing. The relative elevations were such that only a very small quantity could be sluiced directly, so practically all of the material was excavated with drag lines and placed in large piles. It was then sluiced from these piles down into the dam. However, after the dam had reached a certain height the slope in the sluicing line became insufficient; this was partly due, too, to the increased distance of the drag line from the dam. When this point was reached the material was sluiced to a pumping plant located at an elevation of 375 ft. Before being delivered to the pumps, the material was passed through a revolving screen which eliminated all stone over 6 in. in diameter.

On this dam itself a gasoline-driven drag line was utilized to throw up small dikes on each edge to hold the water within the dam and give the sluiced material a chance to settle. Near the center of the dam was a concrete chimney with openings which acted as overflows for the sluicing water. The chimney connected at the bottom with the concrete conduit under the dam. As the dam came up the openings were closed. The dike along the canal was constructed in a similar manner, as it constitutes practically an extension of the main dam.

The canal leading from the reservoir to the intake was excavated for about 3,300 ft. along the east bank of the valley. Terminating the dike in the side hill permitted the construction of a circular intake tower in the canal with only a short length of concrete conduit extending through the dike. Six equal intake openings are located in the half of the tower facing the canal. Each opening is protected by vertical trash racks provided with a compressed air rack raking device, and each opening can be closed by steel stop logs operated by means of manually operated hoists. A self-closing sliding Broome gate is located at the entrance to the concrete conduit in the tower and operated by electric hoist. Ample air vents to the penstock are provided in the intake structure back of the gate. Necessary by-pass pipe connections are provided to fill the penstock from the intake with the Broome gate closed and for filling the intake from the canal with the steel stop logs in position.

TABLE I—TABULATION SHOWING SUMMARY OF WATER USED FOR FILLING THE ROCKY RIVER RESERVOIR IN AN AVERAGE YEAR

| Classification | Water | Amount of Water, Billions of Cu.Ft. | Will Use "Additional" Head of Rocky River Station | Will Use "Additional" Head of Stevenson Station |
|---|---|---|---|---|
| 1 (a) | Run-off exceeding full load flow. | 0.840 | Yes | Yes |
| 1 (b) | Run-off below full load flow..... | 0.760 | Yes | No |
| 2 (a) | Pumped water exceeding full load flow.................. | 1.325 | Yes | Yes |
| 2 (b) | Pumped water below full load flow........................ | 1.105 | Yes | No |
|  | Total.................... | 4.030 |  |  |

The concrete conduit, having an inside diameter of 16 ft., extends only a short distance from the intake tower to the wood-stave pipe line. This wood pipe line has an inside diameter of 15 ft. and extends for approximately 1,007 ft. along the hillside. The average gradient is 0.5 ft. in 100 ft. The intake tower and wood pipe line are of sufficient capacity for the installation in the future of a second generating unit. The wood pipe line joins a steel penstock "Y" connection; one of the two branches is blanked off ready for a second penstock for the future unit, while the other extends a short distance to a Johnson differential surge tank. Freezing of the water in this surge tank is prevented by agitation with compressed air. From the surge tank the penstock drops down the hillside to the power house. The inside diameter varies from 13 ft. to 11 ft. just outside the power house, where there is another "Y" connection, one branch for the generating unit and the other for the two pumping units. Each branch has a Venturi section for measurement of flows.

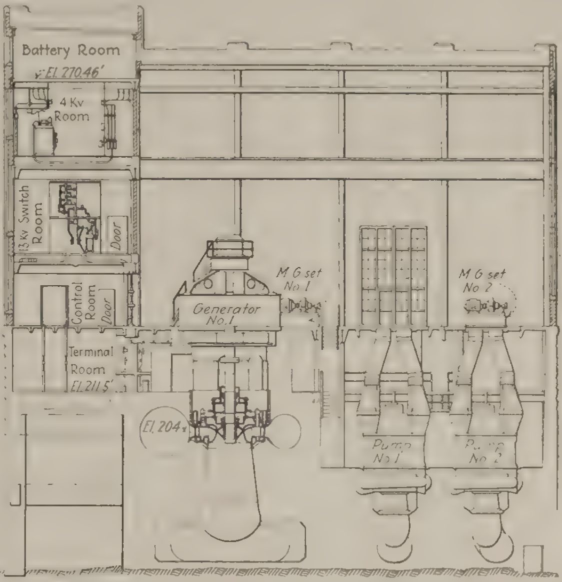

*Fig. 5—Cross-section of Rocky River plant*

### Power Station Building

Like most modern power house construction, the substructure of the Rocky River plant is built exclusively of concrete, with a small amount of steel work to support the lighter floors. The foundation rests on bedrock, which was so close to the elevation desired that little rock had to be taken out or extra concrete put in. The concrete barrel type of construction was used, wherein the entire weight of generator, shaft, runner and hydraulic thrust is carried through a concrete barrel and the turbine speed ring to the foundations. The south end of the building, referred to as the switch bay, is supported on reinforced concrete columns. All the surface of the concrete substructure was coated with a waterproofing compound.

The power house superstructure is of structural steel framework and brick. Precast gypsum slabs provide the foundation for an asphalt built-up roof. All exterior trim of the foundation is of precast cement blocks.

There are four floors in the switch bay with a control cable terminal room below the first floor. The first floor is the control room with the switchboard. The second floor contains the 13,200-volt pump motor bus and switching and the third and fourth floors are used for the 4,600-volt distribution bus and storage battery room.

### Hydraulic Equipment

The hydraulic equipment of the power station consists of one 33,300-hp. vertical shaft turbine and two 8,100-hp. vertical shaft centrifugal pumps. A noteworthy feature of the turbine is the cylinder gate, which replaces the more conventional butterfly or Johnson valves for directly shutting off the flow of water to the turbine. This cylinder gate is built in the turbine in the annular chamber between the pit liner and the speed ring. It is operated from a valve on the generator floor, which controls the admission of water under penstock pressure to the annular chambers above the valve. Positive mechanical locking devices hold the valve either in a completely open or fully closed position.

The centrifugal pump specifications called for a rating of 112,500 gal. per minute (250 cu.ft. per second) delivered against a maximum head of 240 ft. In the discharge line of each pump is a hydraulic-cylinder-operated Dow pivot valve. The intake to each pumping unit can be shut off by a self-closing Treadwell gate, and each intake is equipped with vertical trash racks with air-raking device. Provision is made for the insertion of stop logs in each pump intake and in the two openings of the turbine draft tube.

The generator is of the standard vertical waterwheel type with shaft and exciter. It is rated at 30,000 kva., 80 per cent power factor, 13,900 volts, three phase, 60 cycle, 200 revolutions per minute, with direct-connected exciter rated at 154 kw., 250 volts, compound wound with interpoles. The pump prime movers are vertical synchronous motors rated at 7,900 kva., 80 per cent leading power factor, 13,200 volts (with voltage range of 5 per cent above or below), three phase, 60 cycle, 327 revolutions per minute. Pump motor and spare excitation is furnished by two motor-generator sets, each consisting of 150-kw., 1,200-r.p.m., 250-volt, compound-wound direct-current generator with interpoles direct connected to a 225-hp., 220-volt, three-phase, 60-cycle, squirrel-cage induction motor.

The shaft of the generating unit is of two sections, one for generator and one for turbine, with forged half-flanged sections bolted together upon installation. The turbine shaft has one guide bearing of the babbitted type mounted on the turbine crown plate. Lubrication is provided from a self-contained gear pump driven from the main shaft. For emergency operation a float-controlled rotary, direct-current motor-driven auxiliary oil pump is provided. The generator shaft has a Kingsbury thrust bearing with copper cooling coils and an upper and lower guide bearing of the babbitted type. The lubricating system for the generator shaft bearings consists of a gear pump, driven from the main shaft and located in the lower guide bearing oil pan.

The shaft of the pumping units is one-piece forged steel with a Kingsbury and combined upper guide and thrust bearing with copper cooling coils mounted on the upper spider designed to support the total weight and thrust and a guide bearing between motor and pump, supported in a cast-iron frame of heavy section bolted at the bottom to the upper head of the pump. Lubrication of all bearings on each unit is automatic from a motor-driven gear pump, with a similar pump for spare for each unit.

In the plant there are five distinct groups of electrical equipments:

(a) A 4,600-volt indoor local distribution bus.

(b) A 33,000-volt outdoor tie-in bus for Bulls Bridge station.

(c) A 66,000-volt outdoor main station bus.

(d) A 13,900-volt indoor bus for pumps.

(e) Station service buses.

The 4,600-volt bus is for distribution of power to the New Milford district. The 33,000-volt outdoor bus afforded the most economical arrangement for connecting the Bulls Bridge station (upstream from Rocky River about 8 miles) to the 66,000-volt main transmission system. The 66,000-volt outdoor substation consists of a main and a transfer bus with switching equipment for the two 66,000-volt, three-phase lines to Waterbury, the 30,000-kva. transformer bank stepping down to 13,900 volts and the connection to the transformer banks stepping down to 33,000 volts and 4,600 volts respectively. Space was left in the bus structure so that each of these two banks can be equipped with a separate circuit breaker. The 30,000-kva. main transformer bank has two oil circuit breakers, one of which acts as a transfer breaker. Although the generating voltage is 13,900, the main station voltage is 66,000. If it were not for the two pumping units there would be no bus and no switching equipment at 13,900 volts. The 66,000-volt side of the 30,000-kva. transformer bank is "Y" connected and solidly grounded. The 13,900-volt windings are provided with 40, 50 and 60 per cent taps to obtain with an open delta connection approximately half voltage for starting the pumps.

The 13,900-volt indoor substation is for the sole purpose of supplying power to the pumping units. There are two buses, a full-voltage running bus and a half-voltage starting bus. The connections from the transformer bank to the buses are made with single-conductor cables. The generator leads are connected to the running bus through a set of disconnecting switches, with provision for a future oil circuit breaker. On the generator side of this tap is a non-automatic oil circuit breaker to disconnect the generator from the transformer bank before it is used to supply power to the pumps from the 66,000-volt bus. The two oil circuit breakers connecting each pumping unit to the starting and running buses are interlocked.

### STATION SERVICE BUSES

A 230-volt, 60-cycle, three-phase bus supplies power primarily to the two motor-generator sets, the battery charging set, the sump pumps, air compressor, station lighting, etc. The main 250-volt, direct-current or exciter bus is at present divided into two sections, one for the generator, the other for the two pumps. The 250-volt direct-current emergency bus is supplied from one of the two motor-generator sets. The governor oil pump and the emergency turbine oil pump are normally connected to this bus; if power fails they are automatically switched over onto the 250-volt direct-current battery bus. All the control circuits and small direct-current motors in the plant are connected to the battery bus. The control battery was purchased large enough so that it can perform the double function of control battery and storage battery.

The Rocky River development was designed and built by the U.G.I. Contracting Company of Philadelphia for the Connecticut Light & Power Company in close collaboration with the latter's engineering staff.

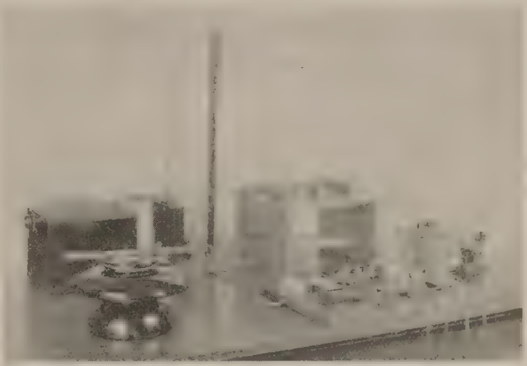
# Pin-Type Insulator Capacitance Tests

By Arthur L. Albert
*Instructor Electrical Engineering,*
*Oregon State College, Corvallis, Ore.*

STUDIES of the capacitance phenomena in suspension-type insulator strings have been of importance in power transmission and it is possible that a knowledge of the capacitance of pin-type insulators may also prove useful to electrical engineers. Very little information is available regarding this subject, and with a view to determining the relations between the capacitance and other test characteristics of pin-type insulators an investigation was undertaken at Oregon State College.

The capacitance of 180 insulators was measured and test values were correlated with certain other insulator test characteristics. A wave-meter and a vacuum tube oscillator as shown in the accompanying illustration were used to make the measurements. The capacitance values were obtained by holding the oscillator frequency constant and observing the difference between the wave-meter condenser settings necessary to produce resonance both with and without the insulator in parallel with this condenser. Capacitances were found to vary from about 8 to 15 micro-mfd. at 500,000 cycles. Large variations in frequency, however, did not materially affect the capacitance. Various factors, such as the size of tie wire, were found to influence results. Also it was found that a relation exists between the capacitance of an insulator and its other test characteristics, particularly the puncture voltage value. This, no doubt, is due to the fact that the puncture voltage and the capacitance are both largely determined by the thickness of the porcelain between the pin and the tie wire and conductor. It is not believed that capacitance is the determining factor in the puncture voltage value at low frequencies.



*Apparatus for measuring capacitance of pin-type insulators using a wave meter and oscillator*

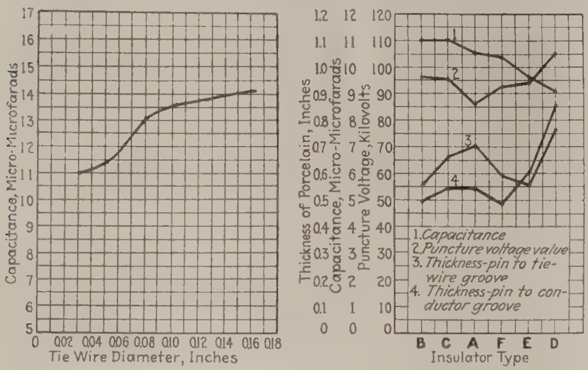
Tests were made on insulators submitted by six dif-

AVERAGE CAPACITANCE, MICRO-MICROFARADS, FOR TEN PIN-TYPE INSULATORS OF SIX MANUFACTURERS

| Manufacturer | 13-17 Kv. | 45-55 Kv. | 66 Kv. |
|---|---|---|---|
| A | 10.54 | 13.12 | 12.31 |
| B | 11.08 | 12.00 | 12.82 |
| C | 11.05 | 11.71 | 14.14 |
| D | 9.10 | 10.88 | 11.97 |
| E | 9.65 | 10.60 | 11.73 |
| F | 10.38 | 11.08 | 10.91 |

ferent manufacturers and will be referred to as A, B, C, D, E and F. These were of three general classes, 13-17 kv., 45-55 kv. and 66 kv. Ten insulators of each class were measured, making a total of 180 tests in all. Individual values of capacitance obtained for the different voltage classes varied between 8.4 and 14.5 m.mfd. For the 13-17 kv. class the range was 8.4-11.8 m.mfd.; 45-55 kv. class, 10.0-14.4 m.mfd., and for the 66-kv. class, 10.6-14.5 m.mfd. Average values for ten insulators in each class are given in the table which appears on page 965.

Tests were made on an "A" insulator of the 13-17-kv. class to determine the influence of tie wire size on measured capacitance. Results are shown in an accompanying illustration. While tests were made on only one insulator, it is evident that the size of tie wire very materially affects the capacitance.



*Effect of tie wire size on insulator capacitance and other characteristics of 13-17-kv. pin-type insulators*

The exact nature of dielectric losses due to an alternating field is not definitely known, and there is at present considerable research being conducted in this field. If there is an appreciable loss in insulators due to the alternating dielectric flux, this loss would probably vary with the capacitance. It was, therefore, thought possible that a relation would exist between the puncture voltage value and the capacitance, since the alternating dielectric flux would heat the porcelain and lower the dielectric strength. The values given in one of the accompanying curves, which were determined by test, show that as the capacitance decreases the puncture voltage value increases. This was what was expected from a consideration of the losses due to the dielectric flux. However, a study of the dimensions showed conclusively that the puncture voltage value at 60 cycles was not determined by the capacitance, but by the thickness of porcelain between the pin and the other electrode. A study was also made to determine the possible relation between the capacitance and corona formation voltage. No consistent relation was found to exist.

### Conclusions Reached

High-voltage pin-type insulators have an appreciable capacitance, varying from about 8 to 15 m.mfd., depending on the design and voltage class of the insulator. An increase in the diameter of the tie wire increases the insulator capacitance.

Frequency of the voltage used in making measurements does not materially affect the measured capacitance.

There seems to be no consistent relation between capacitance and corona formation voltage.

Thickness of the porcelain between the pin or thimble as one electrode and the tie wire and conductor as the other is a very important factor in determining both the capacitance and the puncture voltage value.

The author wishes to acknowledge the assistance of Prof. F. O. McMillan and students of Oregon State College in making this investigation.

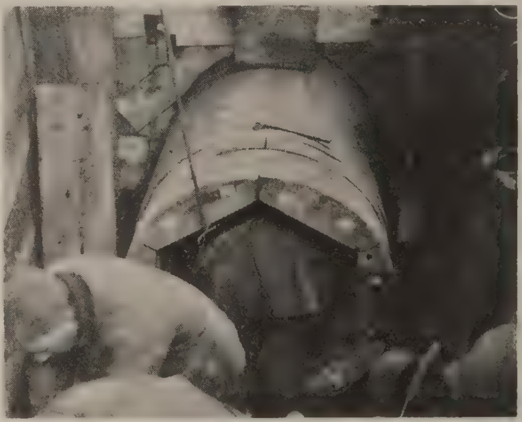
---

## Submarine Cable Approach Tunnel

By M. R. Sumner
*General Superintendent of Construction*
*Byllesby Engineering & Management Corporation, Pittsburgh, Pa.*

During 1927 the Duquesne Light Company installed six cables under the Ohio River at Pittsburgh, Pa. These cables extend from the generating plant on Brunot Island, across the back channel of the river, under the main line of the Pittsburgh & Lake Erie Railroad, to a manhole on West Carson Street, a distance of 1,285 ft. The six cables are each 350,000 circ.mil, 22 kv., lead covered and steel armored. Dredging across the back channel was done by the Equitable Towing & Transportation Company, a subsidiary of the Duquesne Light Company. A trench about 6 ft. deep was dredged in the river bed, the cables were laid in, inspected by a company diver and the trench backfilled by the dredge boat to complete the installation work.

On the mainland it was necessary to tunnel under the four main line tracks of the Pittsburgh & Lake Erie Railroad. A 42-in. outside diameter steel pipe was used for driving the tunnel. This pipe, in 4-ft. sections, had a 6-in. x $\frac{1}{4}$-in. collar on the inside of one end. The first section also had a collar on the outside of the front end, which acted as a driving edge. The pipe was driven through the earth by two 35-ton hydraulic jacks, pressing against an 18-in. driving frame of 6-in. x 6-in. oak, bolted together with staggered joints. A wooden cradle was set to line and grade to start the pipe in the right direction, which was checked twice daily with a transit as the work progressed. Driving was done continuously by three shifts of men and progressed about 1 ft. per hour. The cost of this tunnel was $235.20. Within the tunnel pipe were laid eight 6-in. sewer pipes as a duct line for the cables.



*Cradle and driving frame for steel pipe tunneling*

# Are Customer Sales Overdone?

This might be the interpretation placed upon the recent drastic
decline in the percentage borne by this type
of financing to the total

By H. M. Cameron
*Financial Editor* Electrical World

ATTENTION has been directed recently to an apparent decline in the sale of preferred stock direct to customers by power and light companies through what are popularly called customer campaigns. Total sales of such issues in 1927 fell off to 11 per cent of the year's total financing, against an average of 19 per cent for the seven-year period 1920 to 1926 inclusive. The question arises as to whether or not customer ownership has been overdone. Have the companies been satisfied with the results of campaigns already carried on?

*So much has been said and written on the theoretical advantages to public utilities of selling stock direct to customers that an attempt to secure first-hand evidence with regard to results actually achieved seemed warranted. A questionnaire was sent to representative companies in different parts of the country and several of the replies are presented herewith. The questions asked were:*

*1. To what extent has customer ownership really proved beneficial in improving public and political relations?*

*2. What does the customer-ownership campaign cost in relation to the cost of mortgage bonds or other financing?*

*3. Why is customer ownership declining, or at least standing still, while general financing has increased by leaps and bounds?*

There has been, in fact, no falling off in actual totals of customer-ownership sales, although the proportion has declined materially. The 1927 total was slightly above the revised 1926 total of $236,557,100, although considerably under the 1925 total, which is the highest on record. The 1925 figure was 23 per cent of the total financing for that year. The decline in percentages since that time is due to two factors: A slight reduction in the aggregate volume of customer sales and a sharp increase in senior financing due to declining money rates and to other factors. Public sales of mortgage bonds were more than $1,107,000,000 last year, against $813,860,000 the year before, and the total of debentures sold rose from $158,250,000 to $358,150,000. It is significant that much of this financing was for the purpose of revamping financial structures and retiring high-interest bearing securities, since such financing is better adapted to the purpose than other types. Furthermore, the well-balanced company structures of the industry as a whole permitted of large-scale additions to funded debt, and at the attractive money rates ruling the volume of senior financing naturally increased rapidly.

### Beneficial to Public Relations

Without exception each of a representative group of executives approached by the Electrical World in an attempt to evaluate the real worth of customer ownership agreed that such a policy has an exceedingly important bearing on public relations. P. S. Young, vice-president of the Public Service Corporation of New Jersey, said "it is not unreasonable to say that the adoption by this company of customer ownership of its securities and the consequent dissemination of facts pertaining to the operations of the various public utilities has resulted in improving public relations. Before the Public Service Corporation of New Jersey adopted the popular ownership plan of selling its securities to customers there was hardly a state or municipal election held but that Public Service was used as a talking point by some of the candidates seeking public office. This could have no other than a harmful effect on the Public Service Corporation of New Jersey and its securities. During recent political campaigns practically no mention was made of Public Service by candidates seeking office."

In answer to the same question Chester C. Smith, vice-president and secretary of the Kansas City Power & Light Company, said: "Customer ownership, in my opinion, has been of material benefit in improving the public relations of the utilities. I do believe, however, that the benefit which has been derived has in some instances been greatly overestimated. It has been the personal experience of our company that as soon as our customers have made a nice profit in their securities they immediately disposed of them and invested in other securities. This, of course, does not destroy the good will which has been created, but it did, in effect, minimize it because when the ownership was gone the interest in the company was not so pronounced."

Referring to the bearing of the question on relations, Herbert A. Wagner, president of the Consolidated Gas, Electric Light & Power Company of Baltimore, said: "Customer ownership has undoubtedly proved beneficial in improving public relations. Customer owners take far more interest in the utilities in their communities and their development and financing. Though these customers a better understanding is developed of the reality of stockholder ownership, of the soundness of financing methods, of the necessity for a fair rate of return and the mutual interdependence of the local utilities and local communities."

E. J. Beckett of the Pacific Gas & Electric Company states that there can be no reasonable doubt of the merit of customer ownership in respect to public and political relations. He said: "Out here in California a proposal to put the state in the water and power business has thrice been defeated upon submission to the voters and in each case the stockholders of the central-station companies, now numbering in the neighborhood of 200,000, were without question largely responsible for the active opposition to the measure. These elections afforded a pretty tangible basis for gaging the political value of customer ownership and I believe that its effect on public relations, while hardly susceptible of measurement, has been equally beneficial.

Another reference to the political aspect of the situation is made by F. H. Farnum, manager of the securities department of the Central Maine Power Company. Mr. Farnum says: "In Central Maine Power Company territory during the past ten years the company has been subjected to several severe political attacks. There has been a gradual change in state-wide public opinion from one of hostility to our proposed measures and politics to one of greater friendliness. We believe that this improving public opinion and public relation is in no small measure due to our customer-ownership stock distribution."

Another specific reference to the political aspects of the situation is made by the manager of the investment department of the Southern California Edison Company, who says: "While the primary purpose of customer-ownership financing is to raise money in the local field for capital expenditures, it has assumed an equally important mission as an instrumentality in the promotion of better political, public and employee relations. The defeat of the proposed and pernicious water and power act in California three times in succession by an increasingly large majority may be largely attributed to the hundreds of thousands of power company security holders in the state.

### Saving in Financing Costs

With respect to the cost of financing through the customer-ownership campaigns, a variety of opinions were given. The last-mentioned company states: "Speaking for the Southern California Edison Company only, the cost of selling securities through our customer-ownership campaign is, on an average over a ten-year period, about 60 per cent cheaper than the cost would have been for other modes of financing. The figures for costs are used in the underwriting sense and do not take into account the yield on the types of securities in question which would enter into a computation of real cost of money to the company."

Somewhat different has been the experience of the Potomac Electric Power Company. A. G. Neal, vice-president and comptroller, states: "There are many elements entering into the comparative costs of customer-ownership campaigning as compared to cost of financing through sale of bonds. It is undoubtedly most costly to finance through customer-ownership campaigns, but difficult to put the added value of the good will that flows to the company through this means as compared to that through the sale of bonds."

Referring to the question of costs, the Pacific Gas & Electric Company has had the following experience; "The average spread between the sale price of bonds to an underwriting syndicate and the price at which such bonds are offered to the public is probably from 3 to 5 per cent. Ordinarily, stock financing, on account of the relatively greater risk involved, might logically be expected to exceed this cost. In our own case, however, the cost of selling stock direct to the public has been very substantially below these figures. In the period from the middle of 1914, when this company initiated the customer-ownership plan, to the close of 1926 our average cost per $100 share of selling $64,700,000 par value of the stock direct to the investing public, without any underwriting, was 61 cents. I believe that this figure is, however, very considerably below the average stock selling costs of the industry as a whole.

It is obvious from what has been said that the cost of financing varies according to local conditions. A large company in the Middle West states: "It has been our experience that the cost of financing through customer ownership has been substantially the same as the cost of financing through investment bankers." A large Eastern company states: "Customer-ownership campaigns usually cost less than financing through underwriting or other methods of marketing junior securities." Still another large group with wide experience in customer ownership states: "The cost of money obtained through bankers varies between 3 per cent and 6 per cent, depending mainly on the class of security sold. Costs of the sale of the stock to customers varies principally with commissions paid to employees. In 1927 our costs amounted to slightly over 2 per cent."

### Alleged Decline in Customer Sales

Replies to the third question, dealing with the alleged falling off of customer ownership, also disclosed a difference of opinion. A large Pacific Coast company states: "I should say that this is due to the fact of a plentiful supply of money in the last several years, enabling large blocks of securities to be marketed in a short time by placing the issue through bond and brokerage offices. Many companies not having large construction programs no doubt sold their whole issues in the above manner in a comparatively short time and, therefore, felt no necessity of making any sales themselves locally to their customers during the balance of the year. Personally, I think this is rather a shortsighted policy as the maximum value of customer-ownership campaigns, I believe, is through continuous contact with one's customers in the sale of securities." Answering the same question Mr. Young, vice-president of the Public Service Corporation of New Jersey, states: "This question was anticipated by the 1927 customer-ownership committee of the National Electric Light Association and the statement on page 1 of its report, which is quoted below, practically answers the question: 'It is entirely natural, with the new capital requirements of electric power and light companies varying from year to year and with financial conditions changing from time to time, that the type of securities chosen by the companies shall also vary. It is, therefore, not surprising that occasionally the volume of customer-ownership securities sold in any one year by the electric light and power companies should be less than in some previous year.' "

A slightly different explanation is given by the Central Maine Power Company: "On the Central Maine Power Company system the number of customer owners is not increasing for two reasons: First, because those already owning the stock are increasing their holdings; second, because the tradeouts are almost equal to the number of new stockholders secured. With a limited amount of stock available the number of stockholders will not materially increase. In the case of the Public Service Corporation of New Hampshire there has been in 1927, and will be, a large increase in customer ownership during the present year.

A slightly different aspect of the situation is brought out by Chester C. Smith, vice-president of the Kansas City Power & Light Company, who says: "I am answering this question by saying that, in my opinion, this has been due to some extent to the low yield the securities offered. For example, in the period from 1920 to 1923 stocks and bonds were being freely offered to customer owners on a 7 and 8 per cent basis, whereas in 1927 this yield dropped to as low as 4½ per cent. In other words, customer owners as a general rule are not educated up to the investment quality of a security, but are more interested in the return or yield. This, in my opinion, accounts for the fact that the low-yield securities which were issued in 1927 had to be absorbed by discriminating investors such as insurance companies, trust companies and others investing funds in large amounts for private individuals."

The situation is concisely summed up by Herbert A. Wagner, president of the Consolidated Gas, Electric Light & Power Company of Baltimore, who said: "The sale of junior issues to customers was undertaken at a time when it became necessary and also possible to increase the ratio of junior securities. During and immediately following wartime borrowing had to be resorted to to an abnormal degree, and senior issues rose to unsound proportions. Financing almost entirely by the sale of junior securities followed this for several years. A large part of the more recent financing has been due to the refunding of bonds and preferred stock originally issued on high yield basis. When large issues are called it is necessary to have funds available promptly and surely and underwriting must be resorted to. A large part of the financing for plant improvements and extensions is still being done through customer-ownership distribution of junior securities and probably to a greater degree than heretofore."

### Viewpoint of Electric Bond & Share Company

The attitude of the Electric Bond & Share group toward the customer campaign is of special importance in view of the wide use of this policy resorted to by Electric Bond & Share companies. The following statement by E. B. Lee, statistician of the company, is of particular interest:

> We feel most strongly that public relations are greatly improved by having a large ownership of company stock in the territory served. It is never possible for a public utility company to have perfect public relations, human nature being what it is, but certainly a customer owner looks upon the company that serves him with more friendly eyes than if he did not have his own capital invested in the enterprise.
>
> Your second question has to do with the cost to the company of selling its stock in customer-ownership campaigns as contrasted with the cost of selling the stock in wholesale lots to dealers for distribution. The experience of our associated companies is that there is very little difference in the cost to the company of these two methods of disposing of its preferred stock. There is a direct benefit, however, in having the stock sold locally in that company employees learn more about their company and come into closer financial contact with the public through selling the stock than if the stock were sold by outside bankers.
>
> Your third question is why the percentage of preferred stock sold in customer-ownership campaigns in 1927 constitutes a smaller percentage of the total securities issued by public utility companies than in previous years. This reduction in the amount of preferred stock sold in customer-ownership campaigns in relation to the total securities issued is due to the fact that during 1927 the public utility companies, especially those engaged in the electric power and light business, did a large amount of refunding of securities. Of course, they also sold large amounts of securities for new construction and for additions to properties, but the proportion of securities sold for these purposes to the total sold was less than for previous years.
>
> In this connection it must be remembered that during the years 1917 to 1921, inclusive, it was practically impossible for public utility companies to finance their requirements except at heavy cost. During these years securities sold by these companies carried high interest or dividend rates and were sold at prices to make the cost of money very high. It was not until 1922 that the companies found themselves in a position to finance themselves on anything like favorable terms. The improvement in money conditions continued through the years 1923 to 1926, inclusive, and during this time the companies issued large amounts of securities for new construction and additions and to take care of short-term loans and other indebtedness created during the years when financing was difficult. By the close of 1926 the companies had practically caught up with their construction program and during 1927 the amount of new construction was more normal. During the year, the cost of money having been so greatly reduced, the companies took advantage of the opportunity to refund those issues placed during the years when interest rates were much higher.

### Investment Bankers Favor Plan

Turning from the attitude and experience of the companies to that of the bankers, one might possibly suppose that the investment banking fraternity would not be particularly friendly toward customer-ownership compaigns, since they naturally limit the volume of business available. Interviewed on this subject, Henry R. Hayes, vice-president of Stone & Webster and Blodget and president of the Investment Bankers' Association of America, said:

> The Investment Bankers' Association strongly favors the placement of securities among consumers. We have gone on record as favoring this policy so often that there is little to be added. However, it is of prime importance that only conservative securities be sold and, further, that they be sold at existing market prices. The part-payment policy is a sound method of installment selling and a happy way to encourage thrift. It is best for the consumer to become acquainted with the economics of his utility, but no consumer really should be enticed to buy utility stock unless he has a savings bank account, and perhaps liberty bonds and an insurance policy.

Another large banking house expressed the following opinion through one of its officers:

> As the trend toward customer ownership has become more pronounced, it has become increasingly apparent that the customer represents a consistent source of new money, and while the cost of money obtained through the sale of stock is higher than the cost of money derived from the sale of bonds, it is nevertheless necessary in order to maintain a well-balanced capital structure. Furthermore, if the stock is sold to the consumer (and to the employee) part of this increased money cost might be deemed chargeable to cost of maintaining good relations with customers and employees. The investment banker should have no objections to this method of financing, inasmuch as it is to his advantage for the company to maintain good public relations and a well-balanced capital structure. Furthermore, as it is impossible for most companies to care for their principal financial requirements in this manner, it will not in the long run seriously restrict the business of the investment banker.
>
> At the same time, as pointed out above, by maintaining a good balance of stocks to bonds, the issues handled by the investment banker should be backed by a stronger equity than might be the case if the company did not sell its stock locally. For the banker handling stocks as well as bonds, this might reduce the issues available, but the fact cannot be overlooked that much of the stock is sold to the small investor who, prior to his purchase of the stock of his local electric company, placed his surplus money in a savings bank, a local building and loan association or in local real estate mortgages. Thus it is possible that by selling stock to employees and customers the electric light companies are educating a new class of investor to the possibilities of investing in the securities of corporations. This cannot help but eventually redound to the benefit of the investment banker.

## Power-Driven Take-up Reel Mounted on Line Truck

FIVE trucks of the Northwestern Electric Company, Portland, Ore., are equipped with a line-wire take-up reel attached to the niggerhead of a power-driven winch near the front of the truck. The arms of the reel are mounted on a steel plate which is fastened to the niggerhead of the winch with cap screws, making the reel easily removable. By loosening the screws holding the outer arms of the coil-forming reel the arms may be swung in toward the center for removing the coil of wire.

## Substation Inspections

By O. M. Ward

*Assistant Electrical Engineer Milwaukee Electric Railway & Light Company, Milwaukee, Wis.*

INSPECTION REPORT forms used by the Milwaukee Electric Railway & Light Company for different types of equipment have been described from time to time in the Electrical World. In addition to those forms, there are a number of others of less complexity and detail and also certain summary forms by means of which the chief operator is kept continuously informed of the status of all inspection work undertaken in the various substations.

The shorter forms each cover a definite item. The one on oil switch inspections carries space for notations on the condition of the contacts, of the oil, of the operating mechanism, and of the control. Intervals between regular oil-switch inspections vary from one month to two years, depending upon the equipment or line to which the switch is connected. But inspections are made annually and this form reports the bus voltage, conditions of insulators and connections, cleanliness, and conditions of buses generally. The miscellaneous equipment inspection, which is made at intervals of from six months to two years, is reported on a form which, on account of the impossibility of its being made specific, is mostly taken up with space for remarks.

The operations of automatic switches and contactors are recorded by Veeder counters, the readings of which are taken once a month. These readings, together with identifying descriptions of the equipments and line-ammeter readings, are reported to the chief operator. His accumulated records show the total operations for each month and for the preceding twelve months, and also the monthly average for the particular class of equipment during those twelve months. If the number of operations at any time appears excessive in comparison with the average, a special investigation is made to determine the cause of the condition.

The summary inspection report form, which is kept by the chief operator, consists merely of a date-recording blank, in which he enters the inspection dates for all apparatus and equipment. With this record, he is enabled to keep informed of inspections completed and due, and can, at any time, tell pretty closely the condition of any equipment in any station.

## Revised Handling of Customers' Complaints

By J. W. Williams

*Director Public Relations*
*Binghamton Light, Heat & Power Company*

COMPLAINING customers are the ones who deserve the most attention. Previously all customers' complaints were handled through the meter department. Upon receipt of high-bill complaints the meter was generally tested, but many customers would come back dissatisfied. The customer is seldom interested in what the meter test shows and must be shown where the current actually was used, or must be convinced of the value of the service rendered for the rate charged.

It has been difficult to induce meter men to adopt a sympathetic attitude toward the customer. They are convinced before they start that the meter must be correct, because they have tested many meters and found only a very few fast. This attitude does not appease the customer.

Under our present method complaint men are used who have been trained in every department and who can test a meter if a customer insists. In most every instance they are able to find some cause for the increased consumption that satisfies the customer, so that it is not necessary for the customer to come back and discuss the same complaint all over again. If the increased consumption has been caused by some device that the customer just started using the customer is shown how slight the daily increase in cost is compared with the service given by the particular appliance. This encourages the customer to continue using the appliance rather than neglect its use to reduce the electric bill, as occurred when inexperienced complaint men were employed. The complaint man not only satisfies the complainant but also explains rates and bills, instructs customers how to read meters and shows them how to replace their fuses, etc.

When a complaint is received that cannot be satisfied at our complaint counters a complaint order is made out in triplicate. On this complaint order is shown meter data, last reading, twelve months' consumption and any remarks which the counter clerk has gathered from his conversation with the customer that will be helpful to the complaint man. The record of this complaint is entered on a log sheet, triplicate copy being filed numerically at the counter as a check on the prompt return of original by the complaint man, or in case of a line complaint to assure that the line department completes the work in a reasonable length of time. The original and duplicate of the complaint order go to the complaint man; he retains the duplicate for his records and returns the original to the counter when his work is completed. When the original is returned to the counter the triplicate copy is destroyed.

A comparison of results obtained under the old and new method of handling complaints is interesting:

*Old Method*—Report of meter tester:

"Could find no reason for high bill except that customer is using lights."

*New Method*—Report of a trained complaint man:

"Customer leaves a 25-watt lamp burn all night in bathroom. Children also leave back porch light on frequently all night. I found they had young pups in the cellar that would not eat without lights on, and customer admitted that they forgot these frequently. Satisfied."

This method of handling complaints has reduced special meter tests 75 per cent.

## Electric Trucks Charged at Outdoor Loading Platform

"THE fact that we are constantly purchasing additional electric truck equipment is proof positive that the service rendered has been satisfactory from every angle," said George Ford, superintendent American Railway Express Company, at the recent Electric Truck Conference in New York City. This organization operates a total of 1,528 electric vehicles in eighteen cities of the United States. Of this number 561 are operated in Greater New York. The kilowatt-hour consumption in Brooklyn, Long Island City, New York City and Jersey City totaled 5,401,900 in 1927.

At least 40 minutes per car per day is saved, according to Mr. Ford, by the charging of batteries while still in the truck and while the latter is in position at the loading platform. This practice obviates the necessity of the twice-daily run between the New York garage and the terminal in Long Island City. Weather conditions have, particularly in winter time, seriously complicated the plan, but experience over several years indicates the over-all value of the scheme. There are 125 charging outlets distributed around the outer edge of the platform.

In speaking of the difficulties of winter operation, Mr. Ford stated that the fact that actual failures on electric trucks or the number that were out of service during the winter did not cause the operating department any inconvenience is a fair indication of just what abuse an electric truck may be subjected to and still operate satisfactorily. "While we stored 125 electrics at the Long Island terminal and about 45 gas cars, it was always necessary in the morning to get an electric to tow the first gas car and get it started so that the remainder could be pulled around the platform and started up pending the driver's arrival.

"We at present are operating in New York City some 80 2-ton electric vehicles that are in their seventeenth year and also 120 that are in their twelfth year. It is particularly interesting to note that while years of service continue to accumulate on these vehicles, the repair and maintenance item remains about the same."

It is estimated that 28 per cent of the vehicles operated on an average of twenty hours daily and the remaining 72 per cent an average of fifteen hours.

## Sign Lighting Averages 85 Kw. a Block in Reading

SIGN lighting loads in the eight blocks of the main business section of Reading, Pa., total 680,000 watts, according to statistics of the industrial lighting department of the Metropolitan Edison Company, a subsidiary of the General Gas & Electric Corporation. This unusually high concentration of lighting for a community the size of Reading, approximately 114,000, has been secured largely through practical demonstrations by the company of the results that can be obtained with adequate illumination. Merchants have had proved to them, by installational examples, the sales and attention-arresting values of bright but unglaring effects in window lighting. The same plan has been applied to the improving of sign loads.

*Utility sign and comparative-letter-lighting demonstrate relative publicity values*

The new twelve-story office building of the Metropolitan Edison Company has been topped by a sign bearing the company's name in letters 10 ft. high. It is of a double-face type containing 2,600 25-watt lamps. The effectiveness of this display was such that other neighboring signs appeared dim in comparison. One illuminated-letter device, equipped with 810 10-watt lamps, was changed to 25-watt equipment after a comparative demonstration on one letter had indicated the relative publicity values. As a result of such work an increase of 47,000 watts was made on 21 signs with an appreciable gain in revenue.

Five advertising devices which had been allowed to fall into disuse were reconnected at 32,000 watts, and new signs and poster-board illumination last year amounted to 218,000 watts. In this work the commercial department of the utility obtains estimates for the fabrication and installation of new signs from several companies, leaving the conclusion of final negotiations to the buyer and seller. No signs are merchandised by the utility.

## Value of Campaigns Established

As a result of twelve major sales campaigns during the past year the Georgia Power Company has developed definite evidence regarding the value of such efforts. Out of the total sales, amounting to $1,600,000, more than $1,000,000 worth of goods were sold during the special campaigns. The annual quota was exceeded by $200,000. A comparison of campaign sales with total sales of some of the items is shown in the accompanying table.

SALES AND CAMPAIGN SALES

| Item | Total Sales | Campaign Sales | Percentage in Campaigns |
|---|---|---|---|
| Electric irons | 7,707 | 5,679 | 73.6 |
| Gas ranges | 3,971 | 1,693 | 42.6 |
| Waffle irons | 1,422 | 1,272 | 89.5 |
| Electric ranges | 1,163 | 1,003 | 86.2 |

VALUE OF SALES

| Item | Value | Item | Value |
|---|---|---|---|
| Electric refrigerators | $632,602 | Electric irons | $28,111 |
| Electric ranges | 147,456 | Electric waffle irons | 12,656 |
| Gas ranges | 87,114 | Gas water heaters | 5,763 |
| Radios | 55,720 | | |

Factors entering into the success of the Georgia Power Company's sales campaigns include the division of the state into sections, with a sales force in each; a special price to customers on the items offered during the campaign; free demonstration in the home of the customer, and terms on the articles extending from ten to twelve months. Extensive advertising also played an important part in putting over sales, advertisements being carried in a dozen daily and 40 weekly papers.

## Electric Dehydration of Oil

It happens frequently enough to constitute a problem that crude oil as it is pumped from the well is emulsified with water. Since the pipe line companies will accept nothing but pure crude for transportation through their pipes it is up to the producer to break down the emulsion and take the water out of the oil. The common practice is to apply heat to the oil in a series of cookers. This process of demulsification is now, to a growing extent, accomplished by electric dehydrators, states O. A. Jennings of the Oklahoma Gas & Electric Company.

The oil containing the emulsion is passed through an electrostatic field between two electrodes at a potential difference of about 11,000 volts. The discharge between the electrodes breaks down the emulsion and the water settles out. Aside from making the crude oil acceptable for transportation through pipe lines the Baumé gravity figure of the oil is raised and its market value thus increased. The increase in value is usually sufficient to pay for the treating equipment in nine months or less. The average power consumption of an electric dehydrator is in the neighborhood of 2,000 kw.-hr. per month, varying according to operating conditions between 1,200 and 5,000.

## *Notes on European Conditions*

*Result of Interview with*

Philip Torchio

*Vice-President New York Edison Company*

One visiting Italy and Switzerland is impressed by the remarkable development of railroad electrification. Switzerland has nearly completed her program of electrifying 60 per cent of her railroads. Italy is actively engaged in expanding her railroad electrification and in about a year one will be able to travel from France to Naples on a continuous electrified railroad.

In all the manufacturing plants I have visited in these two countries I have found considerable work in building apparatus for railroad electrifications.

The electric light and power industry in Italy is in a remarkably sound condition. While in the past years the rate adjustments to the depreciated value of the currency have lagged behind the movement of depreciation, with the returned appreciation of the lira of the last year the net returns have materially improved, notwithstanding a slight decrease in gross business during this year of economic readjustment.

One obstacle to the free development of the industry in domestic application is the heavy state and municipal taxes on all lighting bills. This does not apply to power. These taxes average about 60 per cent and are so worked that the electric undertakings are really made tax collectors of this 60 per cent extra for the state and the municipality. If a consumer desires to use any heating or power in his home, he usually demands that the supplying company furnish a separate meter service, so as to avoid the taxes that he would have to pay if he used only one meter for light and power.

The electrification of the industries has perhaps progressed to a greater degree than in any other country. The industrial rates are very reasonable and compare favorably with those of other countries. In the next two years more than 1,000,000 hp. of new hydro-electric plants will be placed in service, thereby making liberal provision for the expansion and growth of electric service in all lines of industrial and domestic activity.

The new telephone companies which, about three years ago, took over the local and interurban state telephone systems have made great improvements. In the large cities certain new, or almost new, details, such as taxi service calls, railroad information service, etc., have been introduced with great success. The state long-distance telephone lines are being entirely revamped, using underground armored cable buried in the ground. The use of overhead cables had to be abandoned on account of the hunters for birds shooting at the cables.

# Industrial Decentralization and Its Effect on Interconnected Systems

*An Interview with*
GEORGE M. VERITY
*President American Rolling Mill Company*
*Middletown, Ohio*

*George M. Verity*

SPREADING of industry over large areas and its effect on speeding up the growth of electric transmission and distribution networks over those areas is pointed out by George M. Verity, president of the American Rolling Mill Company, as an important factor in the wider application of electric power to the home and to the farm. He further said that it is incumbent as a social obligation of industry to promote the development of the electric light and power business if other considerations are equal or not too greatly diverse. In outlining the reason for his conclusions Mr. Verity said: "It is acknowledged that the key to all economic progress is power. It is agreed generally that the prosperity and progress of our country rest on the fact that the American workman is a director of the labor machines rather than a user of his own muscular force. The average utilization of power in American industries is now something more than 4 hp. per worker. This figure is more than double that of twenty years ago. Translated into terms of sweat of the brow, 1 hp. is equivalent to ten men. The American workman of today is the equal of more than 40 men working with their hands and backs. The mechanical power for the operation of machines is best supplied by electric motors. This is self-evident. Ease of control, variety and flexibility of application make electric power pre-eminent for industrial use.

"In addition to its direct service as a multiplier of production, electricity now makes another contribution to industrial progress, a contribution that in the future will increase. It is making more easily possible the locations of factories in small cities and towns. Industrial activity, so far as it is influenced by availability of power, may be removed from congested centers of population. An outworn argument for the locations of industries in so-called "industrial centers" has been that labor is plentiful in those centers. This is true. Labor, of a kind, is usually plentiful. But with that labor industry accepts the evils of a competitive labor market, of labor living in slums and less effective in consequence, of selfishly factional local governments and of labor's disinterest in everything except wages.

"Contrast with this the advantages of the small city. The plants of the American Rolling Mill Company are located in small cities. In these we know that the homes of our employees are brighter and more comfortable. We know that the eight hours of the day remaining after work and sleep are taken out are healthier and happier. We know that recreation is diversified and largely in the out-of-doors. We know that there is a closer contact with and a greater interest in religion than in the large city. We know that social life is at its best. We know that contact of our employees with community and municipal problems is closer and their participation in the administration of local government is on a broader and less sectarian basis. We know that the community of our employees is an important entity in the small city. We know these things because they are the reasons why our plants are located in small cities.

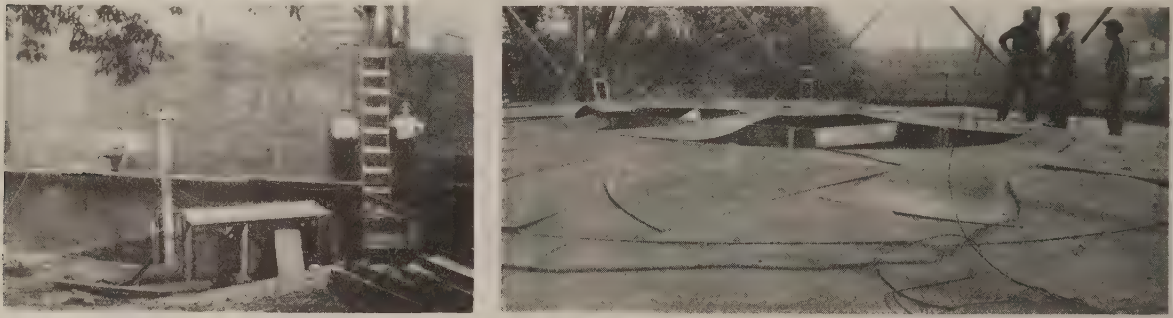
"There is more to the contract between labor and industry than the simple paying of dollars for a day's work, no matter whether the dollars paid are many or few. This is not to say that industry, with paternalistic gesture, should attempt to force on employees, or even offer to them, extra compensation in the shape of community benefits, which quite naturally may be received with resentment rather than thanks. It simply means that the industry is itself a part of the community to which the employees also belong. The industry has obligations to the community in proportion to its size. These obligations must be discharged understandingly and without the possibility of any suspicion that the industry is "running" things. The best way to escape that suspicion is to give no grounds for it, and grounds will not be given if the industry simply does its fair share in local government. The employees, too, have obligations to the community. Their obligations also must be discharged if the contract is to be lived up to. This all boils down to the statement that both employer and employed must develop an awareness of social duties, the performance of which will result in benefit to both. Nowhere but in the small town, where relative sizes are greater, can this condition be realized. This is why "Armco" is committed to the small town.

"I am told that electricity can be economically transmitted 200 or 300 miles. This means that power may be had within areas of such radius from generating plants. I am told also that improvements in steam plant efficiencies smash the idea, popularly held, that electricity must be cheaper in areas where water power is plentiful. This means that industries may be located without special regard to power supply, because power will be plentiful and low priced almost anywhere. In fact, we have gone quite a way on that road already.

"It seems to me that the spreading out of industry over large areas of country, which will be the effect of locating factories and plants in small towns, will greatly speed up the growth of electric transmission and distribution networks over these areas. This will help enormously in the job of bringing electricity to the 6,000,000 American farms that are waiting for it. The farmer now must pay a comparatively high price for electric service because the investment required to serve him is high. The cost to the farmer would be less if there were a few industrial plants taking their power from the same line that he takes his from, thus increasing the revenue factors of the line.

"The production and distribution of electricity is a distinct and separate economic function that, I think, can best be performed by organizations devoted to that work. It is not only true that, in the usual case, electricity can be supplied as economically, or more so, from a central system as it can be generated in a private plant, but from a social standpoint it is desirable for industries to take power from a supply system. This is on account of the fact that the prosperity of the individual rests on the prosperity of the nation. National prosperity, its continuance and enlargement, is in no small degree dependent on the more extensive application of electric power, not only to the industrial plant but to the home and to the farm. This widening application can be maintained and extended only through electricity supply systems. It is then, other considerations being equal or not too greatly diverse, incumbent as a social obligation on industry to promote the largest development of that agency—electricity supply systems—which has so important a rôle in the progress of the country.

"There is the picture. Capital is fast learning that it is a partner with labor on nothing more than an equal basis. The contentment and happiness of labor depend as much on conditions outside the factory as inside. The security of capital depends on the contentment of labor. Labor, respecting self and others, contented and interested in getting the most out of life, gains in respect, contentment and interest as it moves away from population congestion. Industry, for its own good, goes to the small towns. Electricity supply systems, already spread out over the United States in interconnected networks of enormous extent, grow larger and become closer woven on account of the spreading out of industry. The nation continues at accelerated pace toward her destiny of a happy, continuously prosperous and united people."



*Portable equipment speeds welding of gasholder.* *Assembly is simplified by the welding of rolled plates*

Tack welding follows the laying out of the plates upon a temporary structure and precedes the final welding work

## Electrically Welded Gasholder

AN ALL-ELECTRIC arc-welded low-pressure gasholder of 300,000 cu.ft. capacity has recently been completed at Albion, Mich. The construction and design are both the work of the Western Gas Construction Company of Fort Wayne, Ind. The holder, with all lifts elevated to their maximum height, stands 113 ft. 7 in. above the foundation. It has a diameter of 74 ft. and weighs 516,385 lb. plus the weight of the welding rod that was used. This is said to be the largest low-pressure gasholder built entirely by arc welding.

One of the great advantages of using electric welding on gasholders lies in the gas- and water-tight features of the construction, according to F. H. Beebe, vice-president of the Western Gas Construction Company. "Building a gasholder by electric arc welding has inherent practical advantages that recommend it strongly. It simplifies construction and reduces fabricating cost. When a gasholder is made of riveted plates it is necessary to employ the tank shop to lay out and punch all the members. When metallic arc welding is used it is only necessary to lay out and punch the members in the shop for fitting-up bolts. The plates are, of course, rolled to the proper radii in the shops. On this job the plates were assembled in position with bolts and tack welded with the exception of the cups and grips, which were fabricated in the shops and assembled in sections on the ground."

On this gasholder 4 tons of electrode welding rod were used. If a holder of the same size were made of riveted construction $7\frac{1}{2}$ tons of rivets would be necessary. Four "Stable-Arc" welders manufactured by the Lincoln Electric Company, Cleveland, Ohio, placed 21,414 lineal feet of welding. The entire job was carried through almost without a hitch and with much less difficulty than would naturally be expected with a new structural process.

## Wiring Practices Improved by British Organization

THE newly formed National Register of Electrical Installation Contractors has just recently held its first annual meeting at the Institution of Electrical Engineers in London. The chairman, P. V. Hunter, pointed out that the register was not a trade organization, but a body to protect the public from the irresponsible wireman and his shoddy and dangerous workmanship and to raise, by means of a national register, the efficiency and status of installation contractors in connection with the application and use of electricity for any purpose.

The register covers Great Britain, the Irish Free State and northern Ireland. Evidence of competence and responsibility and the occupation of suitable business premises are required as a condition of registration. The number of applications received so far is 1,378 and the number on the register is 1,086. Increasing interest in the advantages of registration is being shown by supply authorities and especially by those who have adopted assisted wiring schemes, many of whom have restricted installation work to registered contractors. No complaints of bad workmanship against registered contractors were lodged during the first year of the register's existence.

## Letters from Our Readers

### *Sales Policies—Not Electric Heat at Fault*

*To the Editor of the* ELECTRICAL WORLD:

Frank expressions of opinions, like T. P. Kindig presented in the April 28 issue on "What Is the Matter with Industrial Electric Heat?" are what the industry needs if it is going to progress. Too many discussions on timely topics are framed to avoid offense and they don't get anywhere. Whenever there is a lackadaisical attitude on a situation that requires action we need some straight-from-the-shoulder punches. Better to make some mistakes than conceal conditions that need correction.

Since Mr. Kindig indulged in expressing himself freely I am going to take the liberty of doing likewise.

First of all, there is nothing the matter with industrial electric heat. The slowness of progress in this development, which will eventually involve a load and energy consumption equaling or exceeding motor applications, is due to weak sales policies and selling methods.

The sooner manufacturers, or utilities, get over talking about who will benefit most by the acquisition of the new load and get down to joint participation, realizing that the benefits to either will justify all the work either can put into promotional work, the quicker will results come. Of course, utilities will get a yearly revenue from each installation, but these installations will also bring manufacturers repeat orders just as early motor installations did. "Passing the buck" never brought results.

The attitude of some combination gas and electric utilities or electric utilities affiliated with gas properties constitutes another major hindrance to the deserved growth of industrial applications of electric heat. It is natural for such companies to protect the investors in gas utilities by not stealing away gas applications and replacing by electric. For the combination companies the net immediate result would be zero. But should these situations put a stopper on all activity to secure applications of electric heat?

Surveys by any utility will show that there are plenty of heat applications to work on which are using neither gas nor electricity. If electric operation will be more beneficial to the customer than gas operation, he should be given electric operation, and vice versa. But the debate between the values of the two services should not be carried into the customer's office. It should be settled before customer approach by the gas and electric salesmen. If there is disagreement, then an executive in charge of both services should referee the decision. Debates between gas and electric salesmen in customers' offices have usually resulted in losing the business to oil.

What value will the existing sales policies of some gas-electric companies have if, a few years hence, customers decide for themselves that they want electric instead of gas operation? Better to sell them now what is best for them, so a lot of embarrassing explaining will not have to be done in the future when they voluntarily make a changeover.

Another reason why some utilities have put so little effort into developing electric-heat applications is because they think that such applications are available only in automobile centers, or where metallurgical furnaces are dominant. They haven't analyzed their market by listing every customer's applications which require heat and classifying the possibilities for electric heat as good, fair or remote. A few companies have or are making such surveys and other utilities will wish they had when they see the progress which will be made by the progressive companies which have had courage enough to appropriate money for a survey.

If utilities will analyze their possibilities for increasing motor loads above those which come from industrial expansion due to population growth many will see that they have to develop new markets.

Assuming a utility as interested in industrial electric heat, why the half-hearted sales efforts in acquiring it? Representation of utilities at manufacturers' sales schools on industrial electric heat would make it appear that there is only enough business to support two or three fair-sized utilities. Can the surveys which a few utilities and manufacturers have made of the potential market be so far astray as that?

As Mr. Kindig pointed out, the sales force that utilities have put on industrial-heat load acquisition is entirely out of proportion to the sales force working on motor applications. If the new business which can be acquired from industrial heat loads is equal to or greater than that from existing motor loads, what is the basis for devoting 10 per cent or less of the sales effort to the coming load and 90 per cent or more to a business which has already been developed. Sales forces should be based on the value of the reasonably obtainable market.

Finally, there should be more accumulation of selling-data ammunition, which will be facilitated by greater co-ordination of utility, oven manufacturer, and electrical manufacturer selling forces. As proof of the lack of fact-selling, I would wager that the ELECTRICAL WORLD'S editorial pages would not be burdened if all the factual data on which specific electric-heat applications have been sold during the last five years had to be published promptly.

GEORGE H. GETTER.

New York City.

### *Overbuilds Reading Railroad with 66-Kv. Lines*

*To the Editor of the* ELECTRICAL WORLD:

I note in the April 7 issue of the ELECTRICAL WORLD, on page 709, three cuts showing transmission structures over the Reading Railroad right-of-way in connection with the Conowingo lines. Unfortunately these are indicated incorrectly as being 220-kv. lines. They are actually the 66-kv. circuits from Plymouth Meeting substation, the 220/66-kv. transforming substation, to Westmoreland substation.

P. H. CHASE,
Engineer Transmission and Distribution Division.
Philadelphia Electric Company.

# Digest of Electrical Literature

## *Hydro-Electric Development and Steam Equipment*

*Hydro Plant Achensee (Tyrol).*—P. Simon.—Last September the Achensee plant, the largest Austrian hydro-electric power station, was put into operation. Two natural Alpine lakes, located 6,500 ft. above sea level, were connected and provide the water supply and storage. From there a quadruple pentstock line, under an average inclination of 45 deg., leads to the power house in the valley, giving a useful hydraulic head of 1,200 ft. The station generates single-phase power at 16⅔ cycles for the Austrian Federal Railways and three-phase, 50-cycle for general power supply. There are installed four single-phase units of 8,000 hp., two three-phase sets of 15,250 hp. each and two more three-phase sets of 31,000 hp. each, totaling 124,500 hp., which will produce an average of 150,000,000 kw-hr. annually. The railway generators are driven by single-runner Pelton wheels, the three-phase machines by double wheel turbines of the same type. Transformers step the 16⅔-cycle potential up to the feeder voltage of 55 kv., the 50-cycle power to 115 kv. The outdoor switchgear is remotely controlled from a switching room.—*Zeitschrift des Vereines Deutscher Ingenieure,* March 24, 1928.

*New Extension to Shanghai's Electricity Plant.*—Upon the completion of the work now under construction at the plant of the Shanghai (China) Municipal Electricity Department the capacity of this station will be 120,000 kw. This addition, made necessary by the increase in the use of electrical energy in the territory served, involves the placement of two 20,000-kw. turbo-alternators. Boilers are provided with pulverized fuel equipment each having a steam generating capacity of 140,000 lb. per hour under normal load and 185,000 lb. per hour maximum at a pressure of 350 lb. per square inch and a temperature of 700 deg. F. The construction includes dust catchers fitted to the stacks to eliminate the dust nuisance often associated with the use of pulverized fuel.—*Far Eastern Review,* March, 1928.

## *Illumination*

*Photoelectric Photometers.*—In a series of three papers in this publication, the methods of photoelectric photometry, experiences and the progress that has been made in developing such devices in one laboratory are given. This method of photometry, which substitutes an electrical eye for a human eye, eliminates many of the former difficulties in photometric work. The general characteristics of the equipment and the possibilities involved in its use have been fully outlined. Four separate systems have been developed and a comparison of the practical application of these several devices has been made and the adaptability of the equipment to commercial photometry indicated.—*Transactions of the Illuminating Engineering Society,* April, 1928.

*Standardization of Methods of Heterochromatic Photometry.*—A. H. Taylor.—Experimental results of photometric tests of twelve colored filters, varying in color from saturated purplish-blue to saturated red, are given in this article. Measurements were made by flicker photometer, using a number of observers and by a spectro-photometer. Integral transmission factors computed from spectral transmission data were in satisfactory agreement with those obtained directly from flicker photometer observations for all but one filter. A proposed standardized method of procedure is suggested by the author for use in heterochromatic photometry.—*Transactions of the Iluminating Engineering Society,* April, 1928.

## *Transmission, Substations and Distribution*

*Horizontal Cooling Ducts on Transformers.*—F. Steckler.—On core type transformers with disk coils narrow oil ducts are provided between the disks to provide oil circulation. The size of these ducts is determined largely by mere assumptions, based on more or less reliable operating experiences. The article approaches this subject mathematically, pointing out how readily overheating, sludging of oil and carbonization of the insulation may occur when these ducts are too narrow. On wide coils oil circulation in a horizontal direction may only be expected at the right and left end of the disk section, while the middle part is stagnant and therefore endangered. The width of the duct should always be proportional to the width of the coil. A greatly improved cooling action could be obtained if the disks were wound with slightly rhombic cross-section copper instead of rectangular strips. This would give the disk coils a slight conical shape and would give all ducts an upward slant. A very small angle would increase circulation materially.—*Elektrotechnik und Maschinenbau,* March 25, 1928.

*Power-Factor Improvement.*—Considerable attention is being devoted by French engineers to the subject of power-factor improvement and the report of an investigation by one company is recorded in this article. As the result of several determinations L'Ouest Lumiere found that power-factor improvement in large plants was generally best effected by readjustment of the size of the motors, by the use of static condensers and by the adoption of synchronous or compensated induction motors. In the improvement of medium-sized plants it was generally found that users preferred to adopt an arrangement for the improvement of the whole plant, which obviated changing the distribution of motors or power transmissions. The arrangement most often employed in France is said to be the synchronous compensator, increased attention being given, it is stated, to the manufacture of smaller sizes. Improvements at the generating station and at different points of the system have been considered at some length and the subject of special tariffs allowing for corrected power factors is discussed.—*World Power,* April, 1928.

## *Units, Measurements and Instruments*

*The Dilatometric Study of Light Metals.*—Max Haas.—The dilatometric study of iron and its alloys by other investigators led the author to systematic dilatometric examinations of light metals and their technically important alloys. The apparatus used in this investigation was the Oberhoffer-Esser dilatometer with oil damping of the dilatometer housing and with the furnace dilatometer tubes and dilatometer casing stand at right angles to the camera. There are two means of optical registration, either in the direction of the furnace on a screen covered with a sensitive photographic paper or by reflection of the light rays on a protographic plate by means of a mirror set at an angle of 45 deg. Investigations were made of pure aluminum; silumin, a pure eutectic aluminum-silicon alloy; aluminum copper alloys and duralumin.—*Engineering* (*England*), March 16, 1928.

*A Method for Determining the Condition of Current Transformers While in Service.*—A method for determining the existence of short-circuited windings in current transformers while the transformers are in service and loaded has been devised and experimented with by one of the member companies of the N.E.L.A. When making this test no measurement need be made on the primary side of the current transformer. This test was devised primarily for installations where it is not possible to interrupt the customer's service and for installations where the voltage of the primary service is of such a high value that it is not possible, from a safety standpoint, to use the split core type of current transformer for a rough ratio measurement. It has been found experimentally that short circuits in current transformers are readily detected by this method, if errors of the order of 2 per cent or more occur at the wattmeter due to the short circuit. It is stated that the method proposed in this report is not advocated as a complete solution for all phases of the problem. The experience with this procedure has been limited to such an extent that it is only suggested that the method may, after exhaustive research, prove as practical as preliminary tests indicate.—*Serial Report National Electric Light Association*, March, 1928.

## *Motors and Control*

*Squirrel-Cage Induction Motors.*—D. B. Hoseason.—The principal features of an electric motor are discussed and the characteristics of the squirrel-cage machine are considered in relation to them. The disadvantages of the squirrel-cage motor are then examined and their importance on certain types of drive is considered. Various methods of overcoming the poor starting performance characteristics are dealt with. The characteristics of high-resistance rotors for both continuously rated and short-rated motors are discussed and the advantages of the double-squirrel cage rotor over many of the alternative proposals, are also considered. A close examination of the starting currents drawn by squirrel-cage motors under various conditions of starting is made and the subject is considered from the point of view of the utility engineer.—*Journal of the Institution of Electrical Engineers (England)*, April, 1928.

## *Electrophysics, Electrochemistry and Batteries*

*New Insulating Compound.* — W. Meyer.—With the exception of porcelain, the best dielectric material obtainable today is rolled or laminated paper, impregnated with artificial resin. Its high puncture strength applies, however, only across the layers. It is neither weatherproof nor fireproof. A Swiss concern has developed a new material, called "Diel," made from a condensation product, which is claimed to be of homogeneous structure throughout, is waterproof, does not burn, is insoluble in hot oil and has a specific weight of 1.35. The new material is manufactured in rods, tubes and plates. Results of a large number of tests are given to show puncture, creepage, arc resistance, flashover and mechanical strength. If these claims are substantiated, which seems to be indicated by practical tests of long duration, this new compound should find a large field of applications for high-voltage outdoor insulation. *Bulletin de l'Association Suisse des Electriciens*, March 22, 1928.

*Electrolytic Iron.*—The production of electrolytic iron received little or no attention even after the successful application of refining copper by electrolysis because of the low intrinsic value of iron and the difficulties of obtaining it in a form suitable for commercial purposes. The electrodeposition of iron suitable for commercial use is stated to be a very difficult problem as compared with the electrodeposition of copper, zinc, lead, nickel and many other metals. Owing to the magnetic properties of the electrolytic iron it offers advantages in the construction of transformers, generators and motors. By using sheets of this material the weight efficiency of transformers may be increased about 35 to 45 per cent; in the case of alternating-current motors and generators an economy of about 16 per cent can be effected in the weight of the iron used. It is well known that the losses tend to increase with the time of service of a transformer and the deterioration of the plates takes place more rapidly as the temperature increases. Electrolytic iron gives no trouble from aging as its crystalline structure is very stable. The author has reviewed the various factors involved in the production of this material and offers an outline of the economic consideration.—*Engineering (England)*, March 23, 1928.

## *Traction*

*Action of High-Speed Breakers for Railway Protection.*—C. Begis.—Statistics indicate that there is one short circuit for every 310 train-miles on electrified main railroad lines. The most successful means of protecting the equipment against possible damages from such short circuits are the recently developed high-speed circuit breakers. With the co-operation of the French federal railway system the author has made an extensive study of this subject and gives a report of his work. More than 500 oscillograms were taken under various short-circuit conditions on the 1,500-volt direct-current system. It is claimed that never before have similar tests been made under actual railway operating conditions on such a large scale. The calibrated oscillograms give an excellent proof of the fast current interrupting action of high-speed breakers. Overvoltages as high as 2,500 and 10-ft. arcs were recorded.—*Revue Générale de l'Electricité*, March 17, 1928.

*French Railway Electrification.* — Chas. J. Webb. — The progress and practices involved in the electrification of the Midi Railway (France) are outlined both as to rolling stock and energy distributing equipment. The project involves a 150,000-volt transmission line for long-distance transmission of energy. Conversion to 60,000 volts is made for general distribution and transformed by means of rotary converters and mercury-arc rectifiers to 1,500 volts direct current for tractive-unit use. A special flexible driving coupling has been devised and is installed in many of the locomotives in connection with this development. Passenger trains are fitted with electric regenerative braking, while freight locomotives have rheostatic electric brakes controlled by varying the field of the motor.—*Electrical Review (England)*, April 20, 1928.

## *Heat Applications and Material Handling*

*Fundamental Principles in the Design of an Electric Furnace.*—Tsunezo Kawasakiya.—It is the contention of the author that the design of electric furnaces and other heat-treating apparatus is far behind that of other electrical equipment, and the object of the present investigation is to establish a technical foundation for this line of engineering. The analytical expression by geometrical quantities for conditions in the surrounding walls of an electric furnace is offered as a substitute for the usual algebraic solutions. Thermal equations have been derived to express the steady distribution of temperature, heat flow and stored energy in the walls through which an electric current passes. Simple relations derived by introducing equivalent physical constants for composite walls; an apparent thermal capacity which is denoted by the steady thermal energy stored in the furnace, divided by the temperature rise and corrected by means of an empirical expression; practical thermal equations applicable for a furnace operating intermittently; economical conditions to be kept in mind in the determination of the general contour of the furnace; resistance of the surrounding walls, and the resistive qualities of the material with the viewpoint of economy and application of the theories developed by means of specific numerical examples are given by the author. It is concluded that the principal value of the discussion rests upon the simplification of the mathematical calculations required through the introduction of a universal analytical expression of geometrical quantity for the surrounding walls.—*Journal of the Institute of Electrical Engineers of Japan*, March, 1928.

## *Miscellaneous*

*Investigations of Lightning.* — L. Binder.—If the time of a lightning discharge is known, the current intensity can be calculated from calorific actions on wires or cables. Based upon past and recent observations, the author establishes a formula for the current to be $i = 9{,}500/\sqrt{t}$, giving values which check closely with Peek's latest observations on steel springs, melted by lightning. Measurements on the duration of discharge were made formerly with revolving cameras, while more recently oscillographic, cathode-ray and klydonograph records have afforded a much higher accuracy. Another method used by the author required a series of graduated spark gaps, finding in every case a total duration of more than 1/100 second. During these tests it was found that the distance of the thunder cloud not only affects the induced voltage but that it has also a decided influence upon the time character of the recorded phenemenon, which means that observations on the ground fail to indicate actual lightning conditions. — *Elektrotechnische Zeitschrift*, March 29, 1928.

# News of the Industry

## Transmission and Transportation

### Developments in These Departments of the World of Power Attract Main Attention at New Haven A.I.E.E. Meeting —Attractive Itinerary of Inspection Trips

NEW HAVEN gave a royal welcome this week to the fifth annual regional meeting and student convention of the Northeastern District of the American Institute of Electrical Engineers, which opened Wednesday morning at the Hotel Taft with a large and enthusiastic attendance. Nineteen papers composed the major business program, and through the courtesy of the New York, New Haven & Hartford Railroad a fine inspection itinerary was provided for delegates and guests, including the recently installed mercury-arc rectifier substations of the Connecticut Company at Bridgeport and Stratford, frequency-converter substations of that company and the Connecticut Light & Power Company at Devon and New Haven, the mercury boiler and turbine under erection for the Hartford Electric Light Company, the Hartford hump yard of the New Haven road, and the Rocky River hydro plant of the Connecticut Light & Power Company at New Milford. Yale University kept open house, and through the courtesy of the department of drama a party was scheduled for Friday evening in the Yale University Theater.

At the opening session on Wednesday morning four papers on transmission and four on measurements were presented. An active discussion of these papers was held in the afternoon. Commenting upon the paper of Philip Sporn, which dealt with the rationalization of system insulation, J. L. Montsinger urged that the 60-cycle flashover value of an insulator disk be used as a yardstick to specify the insulation strength of a transformer. C. L. Fortescue, in discussing this paper, stated that any lightning surge exceeding the 60-cycle flashover value for a fraction of a second would result in flashovers. In his opinion, high-impulse ratio values in line insulation did not indicate immunity from lightning flashovers. In endeavors to reduce line outages he urged the use of ground wires in preference to the brute-force method of adding insulation.

J. F. Peters said he was in favor of co-ordinating system insulation, but that the method advocated by Mr. Sporn was not feasible because insulation values are variable and, as designed, there was insufficient leeway in fixing insulation steps. He thought it would be better to fix one weak insulation point in the system, preferably near terminal equipment. In discussing a paper by W. W. Lewis, which also dealt with line insulation, Mr. Peters said that the ground-wire theory was based on induced strokes, but it was not yet proved that it would be effective on chopped waves resulting from direct strokes.

F. W. Peek discussed these papers and said that the maximum voltage that reaches terminal equipment is the arc-over voltage of the line insulators. When line insulation is increased it is therefore reasonable to increase the insulation strength of terminal apparatus to give the corresponding increased system service.

Closing the discussion, Mr. Sporn said that there was no reason for using insulator flashover values as yardsticks to measure transformer insulation strength. It would be better to specify test waves and use numerical values.

Instrumental measurements of surge effects were featured in papers by C. I. Hall, E. M. Tingley, J. W. Legg and A. F. Hamdi and H. D. Braley. Marked improvement in oscillographic technique was evidenced by these papers. At a technical session Wednesday afternoon papers were presented on railway motor selection, track-circuit shunting, the diverter-pole generator and electric conduction in hard rubber, pyrex glass and quartz.

Various aspects of the supply of power for heavy traction service were covered in five papers presented at a railroad power session Thursday morning. Friday was to be given to a student branch session, inspection trips and an afternoon session on power developments, with special emphasis upon the mercury boiler and Rocky River, by L. A. Sheldon and E. J. Amberg respectively. The annual regional banquet was scheduled for Thursday evening, and the convention was to close with a trip to Rocky River on Saturday. Attractive entertainment was provided.

## Chamber of Commerce for Teamwork

### Main Theme of the Washington Meeting, Where Special Attention Is Paid to Light and Power—Sloan and Pack Speak—R. E. Norton on Power and the Investor

THE sixteenth annual meeting of the Chamber of Commerce of the United States was held in Washington on May 7 to 11. "Teamwork for Prosperity" was the subject of the meeting, which focused attention on present and coming economic currents in the nation's business life and on organized efforts to interpret them.

Sounding the keynote at the opening session on Tuesday morning, Judge Edwin B. Parker, chairman of the chamber's board of directors, declared that unless business purge itself of those "whose acts stigmatize and bring business generally into disrepute," the public will turn loose "thunderbolts of wrath" which will inevitably bring legislative and governmental regulation of business and hamper freedom of initiative. Judge Parker's indictment of those who exploit the public for their private gain was the high light of the session. He reiterated the chamber's opposition to government in business, branded as "business outlaws" those who fail to observe the canons of decency and fair play, called for co-operation in the interest of agricultural prosperity, and warned against flaunting American prosperity before the rest of the world instead of dedicating such prosperity to service.

Three addresses of special interest to the electric light and power industry, because of their bearing on the present legislative situation and also because of their interpretation of the industry to business, were delivered at the session of the Natural Resources Division on Tuesday afternoon. M. S. Sloan of Brooklyn, chairman of the division, told of the conditions and trends in the development of forests, minerals and water, stressing some of the social aspects of natural resources.

Touching water-power development, he said in part:

> Government ownership and overregulation threaten all industries dealing directly with natural resources. Water resources, however, have received the bulk of legislative attention, both state and federal. Numerous attempts are being made to break down our national water-power policy through special legislation which would take major power projects out of the established federal water-power policy and treat them as special projects. Muscle Shoals establishes a precedent for the demand for special consideration in numerous instances. It is a demand for special consideration of the power features of the Colorado River and the Boulder Canyon project that has complicated the issues and delayed much-needed flood prevention measures. The settlement of power questions on the St. Lawrence River development is delaying the settlement of that great international question. The problem does not stop with any individual project. Attempts are being made to consider the whole Ten-

nessee River apart from our national water-power policy because of its relation to Muscle Shoals. And proposals are being made to inject into interstate compacts certain agreements that would bind the whole resources of the Colorado River to the special policy which it is proposed to set up for the Boulder Canyon project. Comparable situations have arisen in projects on the Columbia River. Over one-half of the nation's water resources are today bound hand and foot by legislative proposals and must await the final outcome of these proposals before any development can take place.

The practice of making political capital of this natural resource must end. No reason has become apparent for abandoning the water-power policy which was so laboriously created. In an industry such as the power industry where capital investment is great and where money turnover is slow nothing can be more prejudicial to success than the shifting sands of a changing national policy.

To stimulate a more careful use of natural resources it is not necessary for the American people to engage in business activities through government agencies. Neither is it advisable for them to adventure in government ownership for the purpose of demonstrating how development should be conducted and at what price the product should be marketed. The experiences in government operation give us no occasion for pride.

### GROUP MANAGEMENT

R. F. Pack, vice-president and general manager Northern States Power Company, Minneapolis, spoke on teamwork and group management. Part of his remarks follow:

A really thorough analysis of group management reveals that it is built primarily on its ability to select the best-qualified individuals from this great aggregation of human beings, organize them and put them to work for the benefit of all of us. To some "group management" suggests holding companies, and holding companies in turn suggest some remote organization of selfish financiers devoting their energies to pyramiding profits and enriching themselves at the expense of the public. While there are opportunities for abuse in the group management field as there are opportunities for abuse in every other form of business, the fact is that group management is fundamentally and economically sound in that it provides for organizing and utilizing the best available human ability to operate the best machinery ever devised in the industrial history of the world.

Group management is neither new nor peculiar to the electric light and power business. It exists in one form or another in the field of agriculture and related industries, mining and quarrying, manufacture of food products, of textiles, leather and leather products, rubber and rubber goods, metal and metal products, in the amusement business, the hotel business, retail merchandising and in other lines of business activities. In fact, it is being more and more recognized as the soundest and most logical means of rendering the best possible service to the public at the lowest possible cost.

The suggestion that group management is founded primarily on the organization and utilization of the best available human ability and that this method of operation accomplishes material benefits to the public can be amplified by a consideration of the public utility field.

Not many years ago there were numerous communities which had no electric service at all, and in others it was very inadequate. Good service was obtainable, for the most part, only in the large population centers. In that day each community was served by an individual generating plant built for that purpose. Then came advance in the art of transmitting electricity, with consequent interconnection of steam and hydro generating stations, and in the interconnection of groups of towns each drawing from a common power pool. That was the first step toward group management. It accomplished economies which are now too generally known to need further discussion.

The next step was the formation of holding and management companies which undertook to operate and direct a number of these interconnected systems, located often in widely separated parts of the country. Under this plan of organization hundreds of communities ranging in size from large cities to the smallest crossroad villages are given the benefit of the highest type of managerial skill. After all, isn't it good management which marks the line between success and failure in business? It is not the kind of business that makes that business a success. If that were true, everybody would enter that particular line of business with assurance of success. The thing that makes any business a success is its management. The group management plan of operation of public utilities not only furnishes the highest type of management which can be obtained, but the best available brains in each specialized field. For example, the highest obtainable type of hydraulic engineer is employed. It is his job with other duties to inspect and test waterwheels. The importance to the ultimate consumer of this work is quickly seen when we realize that a loss in waterwheel efficiency of 3 per cent may be equivalent to a loss of 2,500,000 kw.-hr. per year in a hydro-electric plant of 20,000-kw.-hr. capacity.

Group purchases mean concessions in prices. A group management company buying in volume for many properties is able to obtain prices fully 10 per cent lower than those which can be made available to an isolated plant. The significance of this may be appreciated when it is known that one large group company may purchase during the year as much as $30,000,000 worth of materials and supplies.

It is in the field of financing, however, that holding-management companies are able to render the most conspicuous service to the members of their respective family groups. Investment bankers and big and small individual investors scrutinize carefully the public utility seeking capital. They both insist that the company must be either one of considerable size or be associated with a larger group, that its earnings and expenses be about normal, that its property be well maintained, that the securities in which capital is to be invested be so adjusted that they are fairly protected by property and earnings, that the company be well managed and have good future prospects. The group properties come nearer to meeting these demands than do individual plant companies. This is evidenced by the fact that they are able to finance at a uniformly lower rate, which, after all, is the best evidence of their stability.

It will be seen, then, that group management not only accomplishes material saving in dollars and cents, which is being passed along to the ultimate consumer, but it makes available to the smallest community the best brains and the highest type of skill that can be obtained, to the material benefit of the public served.

Speaking of teamwork, Mr. Pack reviewed the work of the electric light and power industry with agricultural colleges and farmers on farm electrification and with the telephone companies on inductive co-ordination. He went on to say:

These examples of teamwork give us pleasurable thrills, but unfortunately we do not always get teamwork in business. There are many forces in this country which are busy night and day, stirring up suspicion and discontent and endeavoring to promote radicalism and indeed socialism in every form. Public ownership is a favorite medium. It happens just now that there are pending in Congress a number of measures which would put the government into the electric light and power business. We appreciate that it is our chestnuts which are in the fire. It is our industry which is immediately threatened, and we are doing the best we can to keep the government out of the electric business, because we consider it the legitimate field for private enterprise.

The United States government already is engaged in various lines of business which by no stretch of the imagination can be considered legitimate governmental functions. Some of our states are in the banking business, flour-milling business, cement business, insurance business and so forth. The municipalities own and operate gasoline stations, coal and wood yards and what not. There is a call here for team work. There is an opportunity for every business man who believes that government, whether national, state or municipal, should refrain from competition with legitimate business enterprise to consider the trend of the times, realizing that his business may come next and that here is a real and direct call for teamwork.

### FINANCING UTILITIES

R. E. Norton, vice-president C. H. Geist Securities Corporation of Philadelphia, discussed electric power and the investor. After a brief excursion into the history of electrical financing, he said:

Prior to 1920 the limited or "closed" mortgage was the only instrument considered conservative. On account of the immense growth of the electrical industry, large sums of money were required, and it soon became apparent that the limited mortgage restricted growth; hence the "open-end" mortgage. At first this mortgage was coolly and pessimistically received; but as time passed, owing first to the restrictions of the mortgage and second to the practice of electric companies, through customer ownership and otherwise, to sell their common and preferred stocks and preserve their junior equities, mortgages of this kind were accepted by the most conservative institutions.

For this reason I believe the mortgages protecting the electric utility securties are more conservative than those that protect either the industrial or the railroad issues in the United States. At first the investor cared and knew little about the mortgage restrictions; but now, as a general rule, the mortgages securing power and light securities are filed, inspected and studied by the large purchasers of bonds, as well as by the insurance companies.

And now consider the psychology of the investor. He has found a security regulated by the state public service commissions—a security in which the gross and net earnings of the properties continue to increase in a steady line, good times and bad; a security protected as a rule by sound mortgages and based on management that shows the highest sort of progressiveness and efficiency. These are the factors that have brought about his conversion.

I remember well the thrill that went through the banking world when, about 1923 or 1924, it was newsed about that the life insurance companies in New York were buying power and light bonds. Less than a month ago such bonds, under certain restrictions, were made legal for New York savings banks. Today electric utility bonds of proper character are being purchased at prices approximately on the same basis as you will find in railroads or other securities of the highest class. The markets are active, and many of the securities are listed on the New York Stock Exchange and other exchanges. There is a demand for the preferred stocks and a strong demand for the common stocks. The demand is based not only upon present earnings, but on future; and it is impossible to say that we have reached a point where the power and light properties, both in efficiency of operation and in popularity with the investor, have come into their own.

An interesting forecast of the probable future trend of taxes, and especially corporation taxes, in the next ten years was made at the Wednesday afternoon session of the Finance Department by Prof. Thomas S. Adams of Yale University. He contended that the burden of taxation on corporations is too high and should be reduced to the actual requirements of the sinking fund. Taxes in the aggregate, he believed, will increase, owing to increased governmental expenditures; but he said they should be more justly apportioned among corporations and individuals. A corporation tax of 10 per cent would in his estimation be more equable and not necessitate raids on the present sinking fund.

# Douglas Attacks Los Angeles Bureau

## Representative from Arizona Says that City Had up to 1925 Spent Nearly $130,000 for Boulder Dam Propaganda—Other Testimony Before Trade Commission

THAT the city of Los Angeles through its Bureau of Light and Power had expended more than $129,000 up to the year 1925 to influence public opinion and the Congress in favor of Boulder Dam was the accusation made before the Federal Trade Commission on Wednesday afternoon of this week by Congressman Douglas of Arizona. In Congressman Douglas' opinion the actual sum spent to date was four times that amount in addition to gifts of oranges and other fruit to members of Congress.

Congressman Douglas' testimony followed that of George F. Oxley of the National Electric Light Association, Judge Davis and Ira L. Grimshaw of the Joint Committee of National Utility Associations and Fred J. Bollmeyer of Cleveland, director of the Ohio State Committee on Public Utility Information. Following Congressman Douglas came Benjamin E. Ling, former director of the Ohio committee, and D. L. Gaskill, secretary-treasurer of the East Central Division of the N.E.L.A. The testimony of these witnesses was similar to that inserted in the record by the other state committees on public utility information.

Congressman Douglas' testimony created quite a sensation in an otherwise drab hearing; so much so that the full commission will consider it with a view to determining whether his testimony comes within the scope of the Senate resolution. Up to the present the Federal Trade Commission has been proceeding on the theory that the investigation was limited to privately owned electric light and power and gas corporations.

Congressman Douglas submitted that, in view of the activities of the city of Los Angeles, through the use of its great political power with relation to the inhabitants of the Owens and Santa Clara Valleys in California, and in view of its activites in expending huge sums of money to influence public opinion and members of Congress to support federal ownership of a tremendous power project, the conclusion is inevitable that the activities by political subdivisions to influence public opinion can be as insidious and as dangerous to the body politic as can be the activities of any other type of organization.

As a part of the record Congressman Douglas filed copies of resolutions passed by the Public Service Commissioners of Los Angeles calling for appropriations to the Boulder Dam Association. The Reclamation Service received $120,000 from Los Angeles and affiliated agencies for the investigation of the Boulder Dam site. More than $19,570 was received by the Boulder Dam Association up to July 19, 1924. Other contributions were read into the record, Congressman Douglas giving amounts and dates. He also called attention to the appropriations of the Imperial Valley Irrigation District, totaling $109,807. One item called for a fair-sized appropriation for the purpose of conducting a Congressional party through Imperial Valley. In addition, a special train came to Washington in 1927, carrying lobbyists for the Boulder Dam bill.

Speeches made throughout the country in favor of Boulder Dam were cited as evidence of propaganda by municipalities, and attention was directed to the great number of Californians now in Washington lobbying for the Boulder Dam bill. The Board of Supervisors of Los Angeles County also appropriated $20,000 in May 3, 1928, for that purpose. On the strength of the showing made Congressman Douglas suggested that the Federal Trade Commission investigate further into the activities of Los Angeles.

### Pennsylvania Activities

When Walter E. Long, who is treasurer of the public policy committee of the Pennsylvania Electric Association, took the stand at the Federal Trade Commission's inquiry into the public utilities on Thursday, May 3, he testified that the Pennsylvania Electric Association derived its revenues from the National Electric Light Association, which, he said, rebates part of the dues paid to it by Pennsylvania utilities. The public policy committee's funds come directly from member contributions. This committee was organized eight years ago to function in an advisory capacity on all matters dealing with general policies of the industry in Pennsylvania.

Mr. Long testified that in recent years there has been no active campaign against municipal ownership in Pennsylvania. The public policy committee, he said, was interested mostly in matters before the state departments and before the Legislature at Harrisburg. Its interest is explained by its obligations to its member companies. It had expended $113,000 since 1922.

Judge Healy, the examiner, asked Mr. Long to identify nine items totaling approximately $20,000 paid from September, 1922, to March, 1928, to the chairman of the committee, Walter H. Johnson. Mr. Long said he understood this money was used by Mr. Johnson for "attorneys and agents" but could not say for what particular purposes, preferring to have Mr. Johnson answer. He admitted the opposition of his committee to Governor Pinchot's "giant power" bills. Attorneys' bills of more than $14,000 each to two Philadelphia legal firms were shown, as well as the payment of $1,000 each to a former state legislator, W. T. Mamsey, and to J. H. Bigelow, chairman of the State Democratic Committee.

Governor Pinchot's attitude partly led to the determination of the Pennsylvania Electric Association to intensify its public relations campaign, Mr. Long admitted. He denied that the association or any of its member companies owned or held the obligations of any newspapers, and he replied in the negative to questions whether they had contributed to a presidential or senatorial campaign.

Mr. Johnson followed Mr. Long. He said he could not recollect what he had done with the $20,000 turned over to him by Mr. Long. "But I can say that not a penny of it was spent in connection with public or municipal ownership," he stated. "Every cent of it was spent honorably and lawfully." He thought some of it went to pay persons engaged to oppose bills at the state capital.

A. G. McKenzie of Philadelphia, director of the state utilities information bureaus of Pennsylvania and New Jersey, testified as to the publicity activities of these bureaus, and A. B. Millar, managing director of the Pennsylvania Electric Association and of the Eastern Division of the N.E.L.A., testified that he had held his present office for only about six months and had been spending most of his time studying the duties and functions of the association.

Documentary evidence, mostly relating to surveillance maintained by public utilities over textbooks on economics used in the schools and colleges of Pennsylvania, was introduced on Thursday. Most of the data were taken from files of the former director of the Pennsylvania Public Service Information Committee, Major Richardson, who is now director of information of the Joint Committee of National Utility Associations.

On Friday Senator Norris declared from his seat that the investigation is revealing "most startling things" as to the methods used by the utility interests to educate public opinion. He referred specifically to efforts to influence the adoption of public school textbooks and to defeat government power projects.

## Hunt Attacks Methods of Boulder Dam Boosters

*Governor of Arizona Wants Two-Sided Investigation, Asserting that Five Dollars Has Been Spent to Further Scheme for Every Dollar Spent Against It*

DEMANDING that the Federal Trade Commission shall investigate moneys expended and publicity methods followed by the friends as well as by the opponents of the Swing-Johnson bill, Governor G. W. P. Hunt of Arizona, whose stand against the bill and seven-state treaty has been repeatedly indorsed by re-election to the chief magistracy of his state, makes the charge in a letter to the commission under date of May 2 that "there is a conspiracy to rob the State of Arizona of valuable resources, to make them available to power companies in the State of California, and that enormous sums of money have been and are being expended to employ lobbyists, lawyers, engineers and newspaper men, and to pay for propaganda; that methods—both legitimate and questionable—have been employed to influence public opinion and to influence members of Congress in favor of the Boulder Dam legislation and to threaten, intimidate, harass and browbeat members of Congress into supporting the Boulder Dam legislation," and that "it could also probably be established that attempts have been made to influence the policy of candidates for the office of President of the United States."

Among other things the Governor says:

> Many of these newspapers articles, by inference and innuendo, charge that the State of Arizona in opposing the Swing-Johnson bill is acting in collusion with and under the influence of the representatives of private power companies. These allegations I challenge, denounce and deny. I am, of course, familiar in a general way with the "evidence" which has been offered to sustain the charges with reference to the alleged activities of the power companies. I am also familiar in a general way with some of the propaganda broadcast by those who are advocating this Boulder Dam legislation, and it is my belief that for every dollar the opponents of Boulder Canyon legislation have spent in opposing it those supporting the legislation have spent five dollars.

Governor Hunt appended to his letter a list of persons—not made public—whom he suggested that the Federal Trade Commission summon for examination on this phase of the matter.

## Power Board Considers Indian Power-Site Claims

The staff of the Federal Power Commission has recently completed a study of the amount, if any, that should be paid the Apache Indians of the San Carlos reservation in consideration of the development of power at the Coolidge Dam in Arizona. The dam is being built by the irrigation division of the Indian Service for the purpose of providing a dependable water supply for the Pima Indians and other users in the Gila Valley above the mouth of Salt River.

The Interior Department appropriation act provides for the generation of power at the dam as a by-product of the development. It also calls upon the Federal Power Commission to report to Congress whether any payment should be made to the Apaches as compensation for the power. Those who have been following the study are not surprised at the commission's report that the Indian lands had no power value independent of the irrigation development and that as the Apaches will benefit from the availability of power at low rates for their own pumping and domestic purposes no further compensation should be made.

A declaration of intention has been filed with the Federal Power Commission by the Fox River Paper Company in connection with its plan to reconstruct the dam across the Wisconsin River at Appleton.

## Middle West N.E.L.A. at St. Louis

More than three hundred delegates to the sixth annual convention of the Middle West Division, N.E.L.A., assembled at St. Louis on Wednesday for a three-day session. A notable address by President Don M. Sterns defending the merger movement, a plea of Chairman J. F. Owens of the Public Relations National Section for fuller appreciation of service on association committees, an able treatment of the rural service question by F. J. Hanlon of Mason City, Iowa, and a defense of utility organization and publicity by Carl D. Jackson were the outstanding events on the first day's program. The ELECTRICAL WORLD's report of the meeting will appear next week.

## Fighting Over Power Bills Goes on at Capitol

*Muscle Shoals Bill Warmly Debated in House, Which Adopts Radical Amendment—Boulder Dam Delay—Flood Prevention Bill Compromise*

CONSIDERATION of the Muscle Shoals bill on May 9 indicated that the House is almost equally divided on the measure. Despite a desperate effort on the part of the proponents of the bill to prevent it, the House voted by 169 to 159 to adjourn. The bill had been brought up on calendar Wednesday and was automatically displaced on the following day by the regular order of business. Unless a special rule be granted, it will not be brought before the House again before Wednesday of next week.

An amendment adopted in the course of the debate makes the bill more radical than ever. It provides that the Federal Power Commission is to determine the rate of any resale of power to the ultimate consumer. Thus, in addition to setting up the government in two lines of commercial business—fertilizer manufacture and the generation of electrical energy—a direct conflict between the rate-making bodies of the states and of the federal government is brought about.

The measure is regarded as one of the most radical ever brought to such an advanced legislative stage in the history of Congress. Representative Garrett, the minority leader, pointed out, in an impasstioned speech, that "for the first time in all the history of the country it is deliberately proposed that the federal government shall go into business for business' sake." The House, however, voted down by 125 to 46 Mr. Garrett's amendment that the government corporation be subject to local taxation and other laws of the states in which it operates to the same extent as would a private corporation engaged in such enterprises. Another important feature of the action taken by the House was the placing of a one-hour limit on all debate.

The National Fertilizer Association is protesting loudly against the failure of the military affairs committee to grant it a hearing.

No little encouraged by an indorsement from the White House and by the inclusion of their legislation on the tentative program of the House, advocates of the Boulder Dam bill conferred May 8 with Majority Leader Tilson in the hope of making arrangements for early consideration of the measure. Mr. Tilson took the position that the House should await the action of the Senate, where the Boulder Dam bill is the unfinished business. This is not satisfactory to the supporters of the bill.

Alterations in the flood prevention bill have been made to meet some of the President's objections to it in the form in which it was originally passed. As amended, it has been accepted by both houses and is expected to have Mr. Coolidge's approval. It appropriates $325,000,000.

## Purchases and Mergers

*Hodenpyl-Hardy and Stevens-Wood Interests Are Consolidated—Arkansas Power & Light Takes Over Southern Edison, Ending Litigation*

IT WAS announced on May 7 that the Allied Power & Light Company has been organized to consolidate the interests of Hodenpyl, Hardy & Company, Inc., and Stevens & Wood, Inc. The new company has contracted to acquire substantial stock interests in the Commonwealth Power Corporation, the Northern Ohio Power Company, the Penn-Ohio Edison Company and other companies. Hodenpyl, Hardy & Company were organized in 1914 and with their predecessors have for more than thirty years been interested in the organization, development and operation of public utility properties. Many of such properties—including the Consumers' Power Company, the Tennessee Electric Power Company, the Central Illinois Light Company, the Southern Indiana Gas & Electric Company, the Illinois Power Company, the Ohio Edison Company, the Illinois Electric Power Company and the Southern Michigan Light & Power Company—are now component parts of the Commonwealth Power Corporation system. Stevens & Wood have for many years engaged in the general engineering and construction business and the managing, supervising and financing activities of public utility corporations. They will continue business as a subsidiary company. Mr. Hodenpyl and Mr. Hardy will have substantial investment interests in the Allied company, but will not actively participate in its operations. B. C. Cobb is chairman and R. P. Stevens is president.

By a million-dollar deal completed April 30 the entire capital stock of the Southern Edison Company was transferred to the Arkansas Power & Light Company by the People's Light & Power Corporation of New York, of which the Southern Edison is a subsidiary. All plants and property of the Southern Edison in Arkansas and Mississippi pass into the control and management of the Arkansas Power & Light Company. The transaction will result in the dismissal of an appeal pending in the state Supreme Court, taken by the Southern Edison Company from the judgment of the Independence County Court at Batesville, Ark., regarding ownership of the electric light and water plants at that place and involving $425,000. (See ELECTRICAL WORLD, May 21, 1927, page 1081). The Southern Edison Company has withdrawn its bid for this property. Included in the transfer is the dam across Big Creek near Pangburn, 14 miles from Searcy, Ark., begun by predecessors of the Southern Edison, and which was almost destroyed by the floods last year.

Stockholders of the Harrisburg Light & Power Company will vote June 25 on whether to sell their holdings to the Pennsylvania Power & Light Company. Both companies are controlled by the Lehigh Power Securities Company.

The Harlem Valley Electric Corporation of Pawling, N. Y., has filed a certificate in the office of the Secretary of State of New York merging the Carmel Light & Power Company. The New York State Electric Corporation of Ithaca, N. Y., has filed a certificate merging the Tusten Light & Power Company. The New York Power & Light Corporation, Albany, N. Y., has filed a certificate merging the Blue Hill Light & Power Corporation. The Eastern New York Electric & Gas Company, Mechanicville, N. Y., has filed a certificate merging the Bouquet Electric Power Company.

The Ohio Public Utilities Commission on May 3 authorized the sale of the Union Gas & Electric Company to the Cincinnati Gas & Electric Company for a consideration of $9,695,778, to be paid with the issuance to the former of 185,000 shares of common capital stock at a declared value of $52.40 per share. The Cincinnati Gas & Electric Company, like the Union Gas & Electric, has been under lease to the Columbia Power Company, a subsidiary of the Columbia Gas & Electric Company. As previously announced, the subsidiary properties will be consolidated as the Cincinnati Gas & Electric Corporation.

The Commonwealth Telephone Company of Chicago has asked the Missouri Public Service Commission to approve its purchase of the Holt (Mo.) Electric Light Company.

Calera, Okla., voted April 30 to sell its city-owned lines and distribution system to the Oklahoma Gas & Electric Company.

After several elections in which proposals to sell the Westville (Okla.) municipal plant were voted down, that town on April 24 authorized sale of the plant for $45,000 to W. C. Tegtmeier and associates of Davenport, Iowa. The vote was 183 to 6.

The Town Council of Hooker, Okla., has accepted the bid of the Inland Utilities Company for its municipal light and power plant subject to confirmation at a special election.

Action taken by the City Council of Tahlequah, Okla., to hold an election on an offer to purchase the city lighting plant for $130,000 cash and "other considerations" has met with opposition from citizens who oppose the sale of the plant or favor another bid, stated at $175,000, and they have appealed to the Governor to interfere.

Oscar Nelson, who has owned and operated the Essex (Iowa) Light & Power Company 28 years, has sold the plant to the Nebraska-Iowa Power Company.

Purchase of the holdings of the Texas-Gulf Power Company by the Texas-Louisiana Power Company, which has its headquarters at Fort Worth, Tex., is announced by A. P. Barrett, president of the latter company. The transaction involves the electric light and power plants at Texas City, Friendswood, League City, Dickinson, Brazoria, West Columbia, Angleton and Strawn, as well as the Wichita Falls Traction Company and some waterworks, ice and gas plants. The consideration was not made public. The Texas-Louisiana Power operates in Texas, Louisiana, Oklahoma, New Mexico, Arizona and Kentucky.

The City Council of Summit, Miss., has voted to sell the local electric light plant and franchise to the Mississippi Light & Power Company for $22,500.

The Northern Electric Company has purchased the Whitewood Power & Light Company's plant at Whitewood, Saskatchewan. This firm has also purchased several other plants in eastern Saskatchewan and will operate them from a central producing plant. The town of Fillmore, Saskatchewan, has sold its municipal power plant to the Montreal Engineering Company.

## Prescott Host to Arizona Utilities Convention

*First Meeting of Newly Organized State Body Proves Highly Successful from Both Business and Entertainment Viewpoints*

THAT the Arizona Utilities Association's annual convention and joint meeting with the Pacific Coast Electrical Association and the Pacific Coast Gas Association, held at Prescott, Ariz., April 26, 27 and 28, in the Hassayampa Hotel, was the best all-around convention to meet in Arizona up to date was the way old convention heads expressed themselves regarding the gathering. With a record attendance of 125 delegates from Arizona, California, Colorado, New Mexico and Texas and an unusually good program, the success of the first convention of the newly organized association was called overwhelming.

On the opening morning President W. C. Hornberger outlined the history of the association, its work and its hopes. A talk on the development of the Salt River Valley by Jasper S. Connell of the Salt River Valley Water Users' Association, in which he outlined the program for irrigation and electrification of the valley, followed. Mayor E. C. Seale and M. A. Pooler of the Tucson Gas, Electric Light & Power Company spoke at the luncheon, and in the afternoon W. L. Frost, president Pacific Coast Electrical Association, made an enlightening talk on "The Commercial Era."

On Friday morning A. R. Baily, Los Angeles Gas & Electric Corporation, read a paper on "Practical Present-Day Distribution Methods" in which he outlined some experiments made by his company. S. R. Knight of the same company took as his topic "Some Applications of Recent Developments of Steam Power Generation" and described, using colored charts, modern methods of obtaining the most kilowatts per unit of fuel. P. G. Spilsbury, president of the Arizona Industrial Congress, spoke on "Public Relations," advising that the public be informed of all activities in easily understandable terms.

The four best essays selected from those submitted in a recent employees' essay contest were read. The winner was Mrs. Jean Roberts of the Tucson Gas, Electric Light & Power Company.

At the evening banquet on Friday a Smoki Indian snake dance provided a novel feature and was accompanied by other enjoyable performances. On Saturday morning the delegates were guests of the United Verde Copper Company at the Jerome-Clarkdale mines and smelter.

Officers elected for the ensuing year are: President, M. A. Pooler, Tucson Gas, Electric Light & Power Company; first vice-president, L. V. Seares, Arizona Power Company, Prescott; second vice-president, A. F. Moriarty, Central Arizona Light & Power Company, Phoenix; executive secretary, Milton G. Sanders, Phoenix.

## Ontario Hydro Rates Raised at Toronto

About eighty-six thousand users of electricity in Toronto have been called upon to pay more for their power and light by reason of an upward adjustment of rates announced by the Hydro-Electric Power Commission of Ontario. On houses of six or seven rooms the increase is about 14 per cent, while in the larger homes of ten or twelve rooms the boost is about 29 per cent.

The minimum rate is now 1½ cents per kilowatt-hour, with 10 per cent discount for prompt payment, compared with 1 per cent per kilowatt-hour, with the same discount, the rate which prevailed for some years. Moreover, consumption in excess of 9 kw. per 100 sq.ft. of floor area will cost 2 cents per kilowatt-hour for the excess consumption, except where consumers use electric cooking ranges, when an additional 200 kw. will be allowed at the 1½-cent rate.

The announcement intimates that the revision upward has been necessary because domestic consumption has passed beyond the limits of offpeak supply. The "object of the adjustment," continues the announcement, "is not so much to collect more revenue from the customers who are using an amount of power comparable with what they used in 1916 as to correct the tendency toward increasing loss which results from larger and larger consumption of excess power sold at a decreasing average rate with an increasing average cost."

The new rates are as follows:

Floor area charge, as at present, 3 cents per 100 sq.ft. per month.

First 3 kw.-hr. per 100 sq.ft. of floor area per month, as at present, 2 cents per kilowatt-hour.

Next 6 kw.-hr. per 100 sq.ft. of floor area per month, 1½ cents per kilowatt-hour.

Consumption in excess of 9 kw.-hr. per 100 sq.ft. of floor area per month at 2 cents per kilowatt-hour, subject to an allowance to customers having electric ranges of an additional 200 kw.-hr. per month at 1½ cents.

Prompt payment discount—One cent per 100 sq.ft. of floor area per month.

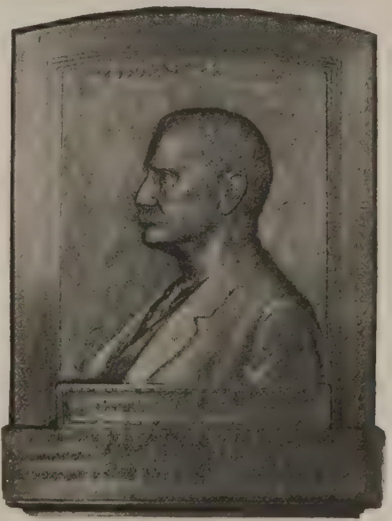
## Refrigerator Manufacturers Organize New Council

Commercial officials of the leading manufacturers of electric refrigerators held a meeting at the Detroit Athletic Club on Wednesday to discuss the advisability of perfecting an organization to promote their common interests. There were present representatives of the Kelvinator, General Electric, Servel, Copeland, Climax, Norge, Dole, Peerless, Zerozone, General Necessities, Cleveland Iceless Cooler and Ice Master companies. The meeting was held at the invitation of A. E. Waller, managing director of the National Electrical Manufacturers' Association, to consider the advisability of forming a refrigerator section of the Appliance Division of the N.E.M.A. rather than organizing a small independent association.

Interest in the discussion focused upon the immediate concern of the manufacturers to bring about more harmonious policies in the education of the public to the advantages of mechanical refrigeration by discouraging destructive practices in competition, and also upon the guidance of proper forms of local regulating ordinances governing the installation of refrigerating equipment. Organization was also seen to offer further opportunities in the field of standardization, industry statistics and similar group activities.

The conference finally voted to form a Refrigeration Manufacturers' Council and tentatively to indorse the N.E.M.A. proposal. The new organization will become effective when ten members sign the constitution and bylaws, which are slightly modified from those prepared after the Walden Woods conference of some time ago. Officers were elected as follows: President, C. K. Woodbridge, Kelvinator Corporation; vice-president, T. K. Quinn, General Electric Company; secretary, G. W. Mason, Copeland Products, Inc.; treasurer, H. E. Blood, Norge Corporation. The directors will be these officers and E. B. Mallory, Climax Electric Refrigerating Company.

## Tablet to Coffin Unveiled



IN THE presence of more than ten thousand employees, the board of directors and a few invited guests, a finely executed bronze tablet honoring the memory of Charles A. Coffin, founder of the General Electric Company, was unveiled at 12:35 p.m. on Tuesday, May 8, at the main gate of the Schenectady plant of that company. At that hour, after music by the General Electric band, Owen D. Young, chairman of the board of directors, called upon Miss Alice Coffin, daughter of the former president, to lift the curtain covering the tablet. E. W. Rice, Jr., honorary chairman of the board, then spoke, paying tribute to the genius, courage, public spirit, modesty and consideration for others that characterized Mr. Coffin.

## Southwestern Public Service Association at Dallas

May 2 to 5 was the date of the thirty-third annual convention of the Southwestern Public Service Association, held at Dallas, with general sessions each morning and meetings of the electric, railway, gas and accounting sections in the afternoons.

After the formal welcome and response on the first day, by E. H. Kifer, vice-president San Antonio Public Service Company, and President M. T. Walker of the association respectively, Secretary E. N. Willis gave an account of the year's accomplishments. Some of the speakers at the general sessions on the following days were John D. Liston of the General Electric Company, J. F. Owens, chairman Public Relations Section, N.E.L.A.; Managing Director Clapp of the N.E.L.A., and Miss Thelma Robinson of the Dallas Power & Light Company, Texas winner in the prize speaking competition, who took for her subject "The Electrocution of Drudgery."

The subjects considered at the meetings of the Electric Section comprised increasing the domestic load, refrigeration, organizing for service to large power customers, safety methods, rural electrification and the selection and training of employees.

More than five hundred men attended the convention. W. H. Burke, Fort Worth, Tex., Southwestern district manager for Stone & Webster, was elected president of the association for the ensuing term.

## Society of Arts and Sciences Awards Medal to Edison

The gold medal of the Society of Arts and Sciences has been awarded to Thomas A. Edison and will be presented to the distinguished inventor at a dinner to be held at the Hotel Astor, New York, on Thursday evening, May 24, at 7 o'clock. Helen Knox, executive secretary of the society, will preside, and the chief speeches will be made by Dr. John Campbell Merriam, president Carnegie Institution of Washington, and Dr. Elihu Thomson. Others who will be called upon are President James R. Angell of Yale, Dr. John H. Finley, Dr. Frank B. Jewett, Charles F. Kettering, Jesse L. Lasky, Secretary Howard McClenahan of the Franklin Institute, Dean William F. Russell of Teachers' College, Columbia University; Prof. Harlow Shapley of Harvard, President S. W. Stratton of the Massachusetts Institute of Technology, Dr. Willis R. Whitney and Arthur Williams. Reinald Werrenrath will sing, and "ether music" will be demonstrated by Prof. Leon Theremin.

Mr. Edison, in accepting the award, requested that should the state of his health at the time of the dinner make it impossible for him to come from Florida, the society permit his son, Charles Edison, president of the Edison Industries, to accept the medal for him.

## Storms Wreck Lines

*Penn Central Light & Power Company, Hard Hit by Belated Blizzard, Recovers Rapidly, Aided by Neighboring Utilities—Trouble in Nebraska*

AMONG light and power companies whose transmission systems were damaged by belated winter storms as April gave place to May the hardest hit was the Penn Central Light & Power Company of Altoona, Pa., whose entire network was put out of commission on the night of Friday, April 27, bringing a cessation of service in all the communities it serves. Through aid from the Pennsylvania Railroad and the Penn Public Service Company of Johnstown it was able to restore partial service, especially to Altoona, from 2 o'clock Saturday morning until Sunday evening, when two of the transmission lines connecting Altoona with the Williamsburg and Saxton plants were restored to service and power sufficient to carry the load was obtained. Forty-eight hours of continuous strenuous labor by a force of several hundred workers reestablished the transmission lines.

The company serves Altoona over a half dozen high-voltage lines. Two of these come from the east, two from the west and two from the south, and they are connected with four power plants. Every one of these lines went down under the weight of the snow, huge steel towers and hundreds of poles were flattened to the earth, and light and power service was cut off. There are 500 miles of transmission lines in the territory and not one was available to use.

Huntingdon, Lewistown, Mount Union and other places to the east were supplied with light and power from Warrior Ridge and Raystown. Martinsburg, Woodbury, Claysburg, Bedford and Everett were all cut off from service, but it was restored to Bedford and Everett Saturday night and to the other places not very long afterward.

The company on Saturday evening sent out a radio call requesting assistance to pull out of the wreckage and re-establish service. It brought a generous response from the Duquesne Light Company of Pittsburgh, which immediately recruited a force of 25 linemen and started them for Altoona, where they began work at 5 o'clock Sunday morning. The Pennsylvania Power & Light Company at Williamsport also picked up the message and sent five experienced men. Workman were handicapped by the deep snow, which in the mountain districts was up to their waists, but strenuous efforts overcame every obstacle, and in a very few days the discontinuance of service was an incident of the past.

A heavy wind and rain storm on May 2 damaged pole lines in central and eastern Nebraska, but prompt replacement was made possible by speedily improved weather conditions. The Nebraska Power Company had to cut out service for half of Omaha the greater part of the following day because river-carried refuse clogged the turbines. The little town of Clarks, in Merrick County, was almost wiped out by a wind of hurricane violence, and all wire companies in that neighborhood were put out of business for several days.

## San Francisco Votes Bonds for Water System

Voters of San Francisco declared themselves emphatically for municipal ownership of their water system when at the primary election on May 1 they voted a bond issue of $41,000,000 for purchase of the Spring Valley Water Company's system and $24,000,000 in bonds for completion of the Hetch Hetchy water supply. Complete returns showed the following vote on the two measures: Spring Valley purchase: yes, 81,302; no, 20,852; Hetch Hetchy bonds: yes, 93,396; no, 11,497. Approval of the Spring Valley purchase has followed four unsuccessful attempts at purchase since 1910, when the proposal was first placed before the voters. The valuation of the property at $41,000,000 was set by the California Railroad Commission.

## Briefer News

**Accounting Section of Empire State Association Meets at Briarcliff Lodge.**—Seven papers on accounting subjects were scheduled for the annual meeting of the Empire State Gas and Electric Association's Accounting Section at Briarcliff Lodge, N. Y., on Thursday and Friday of this week. On Friday President H. O. Palmer of the association was to make an address and Dean Dexter S. Kimball of Cornell was to speak on "The Engineer and the Accountant."

**Klamath Lake Permit of California-Oregon Power Company Opposed.**—A pending congressional measure which would authorize the United States government to be made a defendant in any suit started by the State of Oregon or by an irrigation district to set aside the permit of the California-Oregon Power Company to construct a dam across Klamath Lake at the Link River intake and to use the dam and impound waters for a period of 50 years will probably not be acted upon during this session of Congress, according to information obtained by State Attorney-General Van Winkle, who thinks the congested state of the congressional calendar will prevent. The state is an intervener in an action being taken by the Klamath Irrigation District to dissolve the contract and prevent the construction.

**New Rural Service Lines in Kentucky.**—The Kentucky Utilities Company has announced plans for construction of a new 12-mile, 2,300-volt transmission line from Greenville to serve 40 farms in Caldwell and Crittenden Counties. A 6,600-volt line, 20 miles long, from Cumberland Gap, Ky., to Rose Hill, Va., will serve customers along the route, as well as at Ewing and Rose Hill. A new line from Paducah to West Paducah will serve 36 customers, partly rural.

**New York Edison Rate Hearings to Be Resumed.**—Valuation hearings to determine whether lower rates shall be made for the New York Edison Company, which have been going on at intervals since they were instigated by Mayor Hylan nearly five years ago, are, at the company's own instance, to be continued throughout the summer, despite the city's request that they be postponed till fall. The city is preparing an inventory of property acquired by the company in 1901, maintaining that these figures will constitute the basis of its case. The company maintains that figures covering this property are already available.

**Rate Investigation Getting Under Way in St. Louis.**—The investigation into the rates of the Union Electric Light & Power Company in St. Louis already referred to is about to begin, and the company has filed a new schedule by which 27,303 industrial and commercial consumers will have their rates lowered to bring a total saving of $681,467. The company points out that residential rates were voluntarily reduced $600,000 in 1923, while power rates have been little reduced since 1919. However, the commissioners are also interested in lower rates for residential consumers, and it is believed that the new schedule will be a compromise between the views of the company and the commission.

**Three Guadalupe River Dams Finished, Six to Come.**—Extensions of six months from May 1 in which to carry out six projects for the construction of dams on the Guadalupe River in De Witt and Victoria Counties, Tex., have been granted the Texas Central Power Company by the State Board of Water Engineers. The Texas Central company, an Insull subsidiary, has just completed and placed in use three dams on the Guadalupe in Guadalupe County. The nine plants will comprise most of the desirable power sites on the middle Guadalupe. These are respectively 8 miles below New Braunfels, 5 miles west of Seguin and 5 miles south of Seguin.

**Putting Taxes on the Utilities.**—Light and power companies throughout Ontario County, N. Y., are in for higher taxation as the result of a resolution adopted by the Board of Supervisors at Canandaigua directing the employment of a firm of Buffalo assessment experts at a cost of $7,000 for the direct purpose of increasing tax burdens of public utility corporations. The resolution, adopted after a debate, purports to aim to increase public utility assessments as a forerunner to reducing burdens of smaller taxpayers. The Rochester Gas & Electric Corporation, the New York Central Electric Corporation and the Empire Gas & Electric Corporation are the largest light and power companies in the county.

Cincinnati to Experiment with Municipal Street Lighting.—The Cincinnati City Council has voted money from the public property fund of the city for the purpose of purchasing street-lighting equipment and standards owned by the Union Gas & Electric Company, figures compiled by Edgar Dow Gilman, public utilities director, purporting to show that this will effect a saving both for the municipality and for the property owners. At first only new installations on minor streets will be taken over, it being urged that later, upon expiration of the present lighting contract with the company, the method be extended to the limit of the city's available resources from suitable funds. Comparative estimates on the cost of lighting two actual streets are to be made.

Wisconsin Power & Light Company to Build Small Hydro Plant on Rock River and 132-Kv. Transmission Line.—The Wisconsin Power & Light Company has announced plans for a hydro-electric plant on Rock River at Rockton, Ill., to cost $250,000. A. P. Gale, southern district manager of the utility, announced the project following negotiations by which the Rockton Electric Company, a subsidiary of the Wisconsin Power & Light, acquired the water-power property for $50,000. The present dam will be raised two feet. The new plant will supply power to Rockton and will connect with power lines which are to be built for convenience of Winnebago County rural residents. The Wisconsin Power & Light also announces that it will build a 132-kv. transmission line from the state line at Beloit to Janesville, Wis., and from Beloit to Belvidere, Ill., to connect at the latter city with a similar line running to Waukegan, Ill.

Vermont and New Hampshire Commissions Still Wait Agreement on Connecticut River Jurisdiction.—Recent hearings before the Vermont Public Service Commission on the petition of the Bellows Falls Canal Company for condemnation of farm lands near Bellows Falls, Vt., and the assessment of damages to be caused by raising the company's dam in the Connecticut River 13 ft. resulted in a further adjournment until May 22. It was brought out that the New Hampshire commission has not advised the Bellows Falls company of any decision regarding the pending petition, which asks for a modification of an order giving New Hampshire power preference over Vermont on electricity generated through raising the dam. The Vermont commission intimated that unless a modified agreement can be reached it will decide that it has no jurisdiction in the matter.

New Unit at Zilwaukee Plant to Go in by June 1.—The new 30,000-kw. unit of the Consumers Power Company at its steam plant near Saginaw was turned over for drying-out purposes several weeks ago and will, it is expected, go on the lines by June 1. The plant has also been augmented by five stoker-fed boilers, a condenser and a new coal-handling system designed to care for an ultimate station capacity of 150,000 kw., of which 70,000 kw. is now installed.

Lamme Award for Achievement in Engineering.—At Ohio State University this spring a gold medal will be awarded for the first time from the Lamme foundation, of which the late Benjamin G. Lamme, long the chief engineer of the Westinghouse Electric & Manufacturing Company, an alumnus of the class of 1888, was the donor. The medal, which contains $100 worth of gold, is to be awarded every five years to a graduate in any branch of engineering at Ohio State. Together with a bas-relief of Mr. Lamme, with the dates of his birth and death, 1864 and 1924, it bears a quotation for which he became noted: "The engineer views hopefully the hitherto unattainable."

Threatened Break in a South Carolina Dam Averted.—Engineers succeeded by hard work in averting a threatened break in a waterworks dam 31 miles north of Greenville, S. C., which caused thousands of residents in the South Saluda River Valley to flee from their homes at the end of last week. The threatened structure is described as an earth dam 700 ft. long, 783 ft. thick at the base, tapering to 30 ft. at the top, and 140 ft. high, holding five billion gallons of water. For a time there was thought to be danger to other dams lower down the stream, should the Greenville dam break, and it is reported that the floodgates of a power dam at Piedmont were opened as a precautionary measure. A hundred miles southeast of the threatened dam the great hydro-electric project of the Lexington Water Power Company is under construction, with the fall of 1931 set for its completion. President W. S. Barstow of the General Gas & Electric Corporation, which is behind the Saluda Dam project, scouted the idea of danger to it from future floods or breaks, pointing out that the reservoir to be built and known as Lake Murray will be 33 miles long with an average width of 3½ miles and a maximum width of 14 miles.

Portland, Ore., Asks Rate Valuations of Its Electric Service Companies.—Rate valuations of the Portland Electric Power Company and the Northwestern Electric Company, the two Portland (Ore.) utilities which recently failed to obtain the approval of the city voters to merge their holdings, are asked by Portland authorities in a request to the Public Service Commission. According to Commissioner H. H. Corey, any reduction of rates of at least one of the utilities under consideration will not be confined to that city, nor, he states, will it be possible under the law to confine the investigation to Portland alone. To establish lower rates in the metropolis, he says, it will be necessary for the commission also to require that the Portland Electric Power Company equalize its tariff in respect to service rendered as far as 51 miles south to the city of Salem. The recent action of the commission upon its own motion will have precedence in the matter of the valuation probe of the two Portland utilities, but the commission has signified its willingness to co-operate with the municipal authorities.

Seattle Bill for Municipal Acquisition of Puget Sound Power & Light Plants Killed.—Opposed solidly by the majority group in the City Council, Councilman W. T. Campbell's bill designed to pave the way for acquisition by the city through condemnation proceedings of important properties of the Puget Sound Power & Light Company was killed at a recent Council session. The bill authorized a preliminary survey and appraisal of the company's Seattle distribution system and its Snoqualmie Falls and White River power plants and carried an appropriation of $25,000 to defray the cost of the appraisal. As originally drawn, the Mount Baker power plant was included in the property to be appraised, but the sponsors of the ordinance finally omitted it from the list. Those members of the council who supported the measure declared it necessary on the ground that sooner or later either the company or the city is bound to have a monopoly.

Plans Enlargement of Niobrara River Plant Under Increased Head.—The Northern Nebraska Power Company, which operates a hydro-electric plant on the Niobrara River, near Spencer, announces that it will construct a million-and-a-half-dollar plant at a point 10 miles south and 6 miles east of Spencer, which will increase its annual production from 15,000,000 kw.-hr. to 75,000,000 kw.-hr. The company, through E. A. Forbes, president, has contracted to sell the entire output to the Interstate Power Company, which operates in Nebraska, Minnesota, Iowa and South Dakota, covering a 300-mile-square territory. Mr. Forbes says that peculiar riverbed construction of the Niobrara makes possible the development at the point chosen of the largest hydro-electric plant in the state and the production of electrical energy at a cost below that of any steam plant in the state. The present plant has a 15-ft. drop. The new one will have a 50-ft. drop, thereby adding grreatly to the production possibilities of the site.

---

Beauharnois Project Officially Authorized.—In so far as the Province of Quebec is concerned, the Beauharnois project (Electrical World, March 10, page 523) was officially authorized on April 28 by the signing of an order in Council granting the Beauharnois Light, Heat & Power Company the right to divert 40,000 cu.ft. of water per second between Lake St. Francis and Lake St. Louis on the St. Lawrence for the development of hydro-electric power, most of which will be absorbed by large industrial concerns in the immediate vicinity of Montreal. In addition to paying a yearly rental of $20,000 in advance for the first five years and $50,000 per year for the remaining period, the company has agreed to develop 100,000 hp. during the first five years, 200,000 hp. after the sixth, 300,000 hp. after the seventh and 500,000 hp. at the end of ten years. An announcement that the company would apply to the International Joint Waterways Commission for approval of its plans has called forth criticism in the Canadian Senate, on the ground that such sanction would encroach on provincial rights and that the question of jurisdiction should be settled by negotiation between Canada and the United States.

## *Coming Meetings*

**[A complete directory of electrical associations, with their secretaries, is published in the first issue of every volume. For latest list see Electrical World for Jan. 7, page 80.]**

Arkansas Utilities Association—Arlington Hotel, Hot Springs National Park, May 14-16. R. I. Brown, Arkansas Power & Light Co., Little Rock.

American Society of Mechanical Engineers—Pittsburgh, May 14-17. Calvin W. Rice, 29 West 39th St., New York.

Indiana Electric Light Association (jointly with Indiana Public Utilities Association) — Columbia Club, Indianapolis, May 22-24. William Stokes, 1548 Consolidated Bldg., Indianapolis.

National Electric Light Association—Atlantic City, June 4-8. P. S. Clapp, 420 Lexington Ave., New York.

American Association of Engineers—Hotel Hussman, El Paso, Tex., June 4-6. M. E. McIver, 63 E. Adams St., Chicago.

Electrical Supply Jobbers' Association—The Homestead, Hot Springs, Va., June 5-8. E. Donald Tolles, 165 Broadway, New York.

National Electrical Manufacturers' Association—The Homestead, Hot Springs, Va., June 11-15. S. N. Clarkson, 420 Lexington Ave., New York.

Pacific Coast Division, N.E.L.A. — Hotel Huntington, Pasadena, Cal., June 12-15. S. H. Taylor, 447 Sutter St., San Francisco.

Georgia Electrical Association—Savannah, June 14 and 15. J. J. McDonough, Georgia Power Co., Dublin, Ga.

Northwest Division, N.E.L.A.—Portland, Ore., June 19-22. B. Snow, 1208 Spalding Bldg., Portland, Ore.

Canadian Electrical Association—SS. "Richelieu" from Montreal to Saguenay and return, June 20-23. H. M. Lyster, 712 Power Bldg., Montreal.

American Institute of Electrical Engineers—Cosmopolitan Hotel, Denver, June 25-29. F. L. Hutchinson, 33 West 39th St., New York.

Association of Iron and Steel Electrical Engineers—Hotel Stevens, Chicago, June 25-28. J. F. Kelly, Empire Bldg., Pittsburgh.

American Society for Testing Materials — Chalfonte-Haddon Hall, Atlantic City, N. J., June 25-29. C. L. Warwick, 1315 Spruce Street, Philadelphia.

East Central Division, N.E.L.A.—Cedar Point, Ohio, July 10-13. D. L. Gaskill, Greenville, Ohio.

## Recent Court Decisions

Company Responsibility for Mishaps Alleged to Be Attendant on Right-of-Way Construction.—The Court of Civil Appeals of Texas has sustained a jury finding of company responsibility in Kleinstein vs. West Texas Utilities Company. This was a damage suit brought by a land owner against the owner of a transmission line built over his land. Alleged losses incurred included the escape of cattle through a gap in the owner's fence said to have been made by the company. This claim was properly submitted to the jury, the court held, as was the damage sustained by the alleged cutting of the right-of-way to an excessive width. (3 S. W. [2d] 882.)*

---

Lack of Legal Evidence of Ownership of Pole Absolves Company Whose Stencil It Bore from Liability for Accident.—A pole alleged to belong to the Lowell Electric Light Corporation fell when a lineman employed by the city climbed it to repair wires belonging to the city, and he was injured, a damage suit (Lynch vs. Lowell Electric Light Corporation) resulting. The Supreme Judicial Court of Massachusetts has reversed a verdict for the plaintiff on the ground that since no permit for the erection of this pole, which had stood for twenty years, could be found in the city's records ownership was not proved, the existence of the pole was a nuisance and the city in attaching its own wires to it was a trespasser or at most a licensee to whom the company owed no duty. "Although the pole in question bore a number and a metal strip with the letters L.E.L. stenciled thereon, there is no claim that there were wires of the defendant on or attached to the pole at the time of the accident," the court said. "On the uncontradicted evidence that the defendant after the accident removed the fallen pole, cut off a section and destroyed the remainder of it, with other circumstantial evidence, the jury would have been warranted in finding that that pole was then owned by the defendant." (160 N. E. 413.)

## Commission Rulings

"Going-Concern" Value Not to Be Estimated on Percentage Basis.—In adjusting a complaint made by the city of Erie against the Mutual Telephone Company the Pennsylvania Public Service Commission found fault with the method of estimating "going-concern" value by percentages followed by both contestants, saying: "The commission will not accept such a method as the proper procedure for arriving at this value. The going-concern value of any public utility, when such value exists, must be determined from the circumstances of the particular case." The commission cut down the company's figure—$407,061—and the city's figure—$340,000—to $300,000, basing its own figure on a consideration of the character of the plant and a study of its operations, together with the advantages to the public derived from a recent consolidation.

---

The Argument Against "Going-Concern" Value as a Factor in Rate Base.—In determining rates for an Indiana telephone company recently the Indiana Public Service Commission made a radical departure from usual methods by giving no consideration at all to "going-concern" value. "Going value and overhead costs have been the bone of contention in practically every big rate case that ever has come before this body during my years of service," Commissioner John W. McCardle, who wrote the order, declared: "Its elimination in this case marks a step forward in relieving the patron of an added burden and in reducing the actual costs incurred during rate proceedings. The patrons of a utility will be very slow to agree that any amount of going value should be added to capital account and a rate of return received on it; in fact, with the safeguards surrounding and protecting a utility from competition which are provided by the Indiana utility law, it is doubtful if going value ever should be added, for the reason that the law grants a monopoly, the consumers pay the cost of building up the business and an adequate return on the investment always is guaranteed the investor from the beginning. No two engineers agree as to what constitutes going value. Some say good will, some an opportunity to do business; some maintain that no expense is incurred to get new business after the business once is established." Continuing, the order says: "It is refreshing to note that the petitioner has not offered in evidence any appraisal of its property on the theory that its present fair value based on what it would cost to reproduce the property new is greatly in excess of what it really cost, as is usually done, but is content to rely on the book cost of the property as being a fair rate base in this case. This gives the commission an opportunity to allow a return upon the petitioner's investment, which is quite rare in present-day rate making. We wish to commend the attitude of the petitioner in this respect and to remark in passing that if more of the utilities would assume this attitude, a long step would be taken to promote harmony and a better public relationship between the patrons and the utility and reduce the rate-making process to a fairer and easier task." An increase designed to insure 7 per cent on the investment was granted by the commission.

# News About Men of the Industry

## *D. N. Lewis Assumes New Duties in Chicago*

Dwight N. Lewis, formerly commerce counsel of the Iowa Railroad Commission, is now vice-president of the United Public Service Company with offices in Chicago. Though a lawyer by profession, Mr. Lewis has long been prominently identified with the public utility industry. Mr. Lewis is a native of Iowa and a graduate of the Drake University Law School at Des Moines. For approximately 30 years he has been connected with the Iowa commission, at first being the whole office force, in charge of accounting, secretarial work, rate work and reporting. Gradually he advanced to be secretary and later counsel, which position he held for six years. Finally he became a member of the commission, and in 1927, after serving several terms, he was named commerce counsel. It was from this office that Mr. Lewis resigned to remove to Chicago. He has always devoted considerable time to the affairs of the National Association of Railroad and Utilities Commissioners and his successful committee work in that association culminated in his election to the presidency in 1922.

*D. N. Lewis*

**Dr. Felix Deutsch**, head of the Allgemeine Elektrizitäts - Gesellschaft, has just celebrated his 70th birthday. Dr. Deutsch paid his first visit to America last fall.

**L. L. Bailey**, commercial manager of the Keystone division of the West Penn Power Company with headquarters at Ridgway, has been promoted to the position of assistant to W. S. Finlay, Jr., president of the West Penn Electric Company, the parent company of the West Penn Power Company. He will make his headquarters in Pittsburgh. For the past 4½ years Mr. Bailey has been commercial manager of the Keystone division. He joined the company in August, 1923, as power engineer and on Jan. 1, 1924, was appointed to the position of commercial manager of the Keystone Power Corporation. On July 1, 1927, when the Keystone Power Corporation was merged with the West Penn Power Company, he assumed the duties he is now relinquishing.

**N. G. Harvey**, who recently resigned as president of the Illinois Electrical Supply Company and of the Electric Association of Chicago, was the guest of honor at a farewell luncheon given at the Union League Club, Chicago, April 30. The occasion marked the withdrawal of Mr. Harvey from the business life of Chicago to reside permanently in California. W. W. Low, president of the Electric Appliance Company, was the toastmaster. Twenty-three men attended, all of whom have been active in local electrical circles.

**M. L. Hibbard**, formerly chief operating engineer of the Northern States Power Company, who joined the Electric Bond & Share Company, New York, early this year, as announced in the Jan. 21 issue of the Electrical World, has been assigned to the Idaho Power Company, Boise, in the capacity of assistant general manager.

**C. P. Potter**, engineer in charge of large motor and transformer divisions of the Wagner Electric Corporation, St. Louis, Mo., has been elected chairman of the St. Louis Section of the American Institute of Electrical Engineers. Ever since he joined the Institute at the time he graduated from the University of Illinois, in June, 1909, he has been serving on various committees, and last year served as vice-chairman of the St. Louis Section.

**J. E. Aldred** of Aldred & Company, investment bankers of New York and chairman of the board of directors of the Consolidated Gas, Electric Light & Power Company of Baltimore, returned April 30 aboard the *Leviathan* from an inspection trip of the hydro-electric properties in France and in Italy in which the International Power Securities Corporation has invested. Mr. Aldred is president of the International.

**M. F. Simmons** has been appointed assistant to the vice-president in charge of General Electric manufacturing, according to an announcement made by C. C. Chesney, vice-president of that company. Mr. Simmons, who has been general supervisor of production, will continue in that capacity and will take over such other duties as may be assigned from time to time. He entered the service of the General Electric Company 25 years ago. For fifteen years he was in charge of the cost department at the Schenectady plant, and in 1921 was made assistant to the manager. Three years ago he was appointed general supervisor of production on the staff of the vice-president in charge of manufacturing.

## *F. S. Dewey General Sales Manager in Cincinnati*

Fred S. Dewey, vice-president in charge of lighting and power sales of the Kansas City Power & Light Company, has severed his connection with that utility to become general sales manager of the Union Gas & Electric Company, Cincinnati. Mr. Dewey has been identified with the Kansas City utility since 1918, when he became assistant general manager, and a few years ago, when the company was reorganized, he became a vice-president in charge of power and lighting sales. A native of Murray, Iowa, Mr. Dewey entered the public utility field immediately following graduation from the Iowa State College. His early experience was in the operation of the steam and gas plants of the Tri-City Electric Company, but he soon transferred his interests to the selling branch of the industry as power salesman.

*F. S. Dewey*

In 1915 he removed to Muscatine, Iowa, to affiliate himself with the local railway company and two years later he was appointed general manager of the Muscatine Light Company, the position he held until he became assistant general manager of the Kansas City property. Mr. Dewey has been active in the American Institute of Electrical Engineers, the Missouri Association of Public Utilities, the Kansas City Electric Club, the American Society of Mechanical Engineers, the Middle West Division of the National Electric Light Association and other societies.

**Samuel Insull**, president of the Commonwealth Edison Company, Chicago, arrived in New York May 8 aboard the White Star liner *Majestic* after a short trip abroad.

**Herbert A. Wagner**, president of the Consolidated Gas, Electric Light & Power Company of Baltimore, who recently was elected a director of the Baltimore Association of Commerce, has also been elected a vice-president.

## *Wentling Directs Research for Cedar Association*

John P. Wentling has been appointed director of the research division of the Western Red Cedar Association with headquarters at Minneapolis. Mr. Wentling, who has held a chair in the division of forestry, University of Minnesota, is recognized as one of the foremost authorities on wood technology. He received his professional training in forestry at Yale University, which was supplemented by practical experience obtained during a four-year connection with the United States Forest Service. After spending two years as instructor in wood technology at the Pennsylvania State Forest School, in 1908 he joined the teaching staff of the University of Minnesota in the division of forestry. During his affiliation with that institution he has organized and developed courses in wood technology and forest products as a major field of study in the division of forestry.

*J. P. Wentling*

In addition to his academic work, Mr. Wentling has frequently been called upon as consultant by outside interests. He is well known among the industries producing forest products, having addressed many state and national lumber organizations as well as various engineering societies.

A. Wainright, formerly operating vice-president of the Inland Power & Light Corporation, has resigned to affiliate himself with A. E. Fitkin, formerly owner of the Inland properties and now active in utility affairs in Los Angeles.

A. D. Babson, assistant manager of the central-station department of the New York district of the General Electric Company, retired May 1 after 37 years of active work with the General Electric Company and its predecessor, the Edison General Electric Company. He entered the employ of the Edison General Electric Company in New York as an estimator and after the consolidation of that company with the Thomson-Houston Company he became engineer of the Washington office. He subsequently was identified with the Baltimore office, the New England district and for a while he was assistant to the late Gen. Eugene Griffin, vice-president of the company. In 1903 he was appointed manager of the supply department of the New York district, which position he held until a few years ago, when he became assistant manager of the central-station department, the supply department having been divided into other company departments.

George W. Mason has been elected president of Copeland Products, Inc., manufacturer of electric refrigeration machines, Detroit, succeeding William Robert Wilson, who becomes chairman of the board. Mr. Mason became vice-president and general manager of Copeland Products, Inc., in March, 1926. He had previously established a reputation in production circles as works manager for the Chrysler Motor Corporation.

## *T. G. Nee Becomes President of Acme Wire*

Thomas G. Nee of New York has been elected president of the Acme Wire Company, New Haven, Conn., to succeed Victor M. Tyler, who retired. Mr. Nee is a graduate engineer of the University of Wisconsin. From 1905 to 1917 he was connected with the Mexican Telephone & Telegraph Company as vice-president and chief engineer in charge of all the company's operations in Mexico. Subsequently he spent ten years with the Allied Machinery Company of New York, which was owned by the American International Corporation of that city, as president of its most important subsidiary, the Horne Company, Limited, in Japan. He made a notable success of this undertaking, particularly during the trying years following the war.

Mr. Nee has had a broad business training in lines that make him thoroughly familiar with the products of the Acme Wire Company. His long connection with the telephone and telegraph industry familiarized him with coils, wire of all kinds, condensers and other electrical wire products. Mr. Nee was also elected a member of the board of directors of the Acme Wire Company to succeed James T. Moran, resigned. James W. Hook, president of the Geometric Tool Company, New Haven, was elected chairman of the executive committee of the Acme Wire Company and William G. Redfield, president of the New Haven Bank, was elected a member of the board of directors of the Acme organization to succeed James E. Wheeler, who has resigned.

*T. G. Nee*

# Obituary

George Offor, pioneer in the electrical industry in England, died recently at his home in Sydenham, London. Mr. Offor had celebrated his 101st birthday just a few days prior to his death.

Paul T. Brady, special representative in New York of the Westinghouse Electric & Manufacturing Company, with which he had been associated for 34 years, died suddenly May 3 at the home of his son in Portland, Ore. A graduate of Phillips Exeter Academy, Mr. Brady had been affiliated with various branches of the electrical industry since 1881. During his connection with the American Telephone & Telegraph Company he helped to extend the telephone system through the southeastern portion of New York State, and after joining the Thomson-Houston organization in 1890 he became its manager for the State of New York and the Middle West. In 1894 he was appointed New York State manager for the Westinghouse company with headquarters at Syracuse, but in 1907 he removed to New York as special representative. Among the public utilities which he helped to develop are the Rochester Gas & Electric Company, Niagara, Lockport & Ontario Power Company, Central Georgia Power Company, Virginia Power Company and the Southeastern Power & Light Company. In commenting on Mr. Brady's death, E. M. Herr, president of the Westinghouse company, said: "Mr. Brady was one of the pioneers of the electric light and power industry. Combining technical electrical knowledge with financial ability, he has left behind his as a monument more than a score of successful electrical systems." Mr. Brady was 71 years of age.

Hugh K. Prichitt, head of Prichitt & Company, investment bankers of New York, and a member of the board of directors of the Dubilier Condenser & Radio Corporation, died April 27 at his home in New York after a week's illness. At the time of his death Mr. Prichitt was an officer and director in several industrial enterprises.

# Financial and Statistical News

## *Markets Exceedingly Active*
## *Preferred Stocks Firm*

WITH further merger rumors and exceedingly heavy buying, the utilities securities markets have had one of the busiest weeks this year so far. Prices of several power and light common stocks have shown gains for the week of anywhere from five to twenty points. Among the most active issues were Columbia Gas & Electric, which advanced twelve points, and American Gas & Electric, which gained seventeen points and touched a new high of 167. Middle West Utilities took a further jump of seventeen points to a new high of 169, and Public Service of New Jersey continued its upward movement with a gain of about ten points to a high of 66⅜. Smaller gains are recorded in the case of several other issues, such as Commonwealth Edison, Edison of Boston, Philadelphia Electric, Southern California Edison, Electric Investors, etc.

Preferred stocks of the power and light companies continue to show strength, regardless of higher money rates, and prices are well maintained in the bond market with a marginal upward tendency, especially in the case of the higher grade issues.

## April Financing Reaches Total of $279,535,000

REACHING a total of $279,535,000, power and light company financing for April was more than double that for April of last year and accounted for almost one-half of the total volume of financing this year to date. This brings the total for the first four months up to $609,941,852, against an aggregate of $612,390,500 for the corresponding period of 1927. In other words, the volume of financing so far this year is keeping pace with the unprecedented record made last year.

Although it is impossible as yet to state accurately what proportion of the above financing constituted refunding operations, it may be assumed that at least $200,000,000 was for this purpose. Some of the largest issues of the month were almost entirely for refinancing, and the gain in interest charges exceeded 2 per cent in some instances.

A comparison of the totals by months this year and last follow:

| | 1928 | 1927 |
|---|---|---|
| January | $98,850,000 | $223,859,000 |
| February | 103,255,500 | 166,000,000 |
| March | 128,301,352 | 96,775,000 |
| April | 279,535,000 | 125,756,500 |
| | $609,941,852 | $612,390,500 |

## Allis-Chalmers Billings Up 6.4 per Cent

Billings for the first quarter of 1928 of the Allis-Chalmers Manufacturing Company show an increase of 6.4 per cent over the corresponding quarter of 1927. Earnings on a comparable basis also reflect an increase inasmuch as there was no fixed charge for debenture interest in the early months of 1927. Entire earnings were available for both preferred and common dividends. In the first quarter of 1928, the preferred stock having all been retired in July, 1927, earnings equivalent to $2.60 per share accrue wholly to common stock holders.

Bookings for the first quarter of 1928 were $8,370,537, against $7,833,622 for the first quarter of 1927. Unfilled orders as of March 31 were $9,973,862.

## *Security Issues of Electric Service Companies in April*

| Name of Company | Amount of Issue (Par Value) | Period Years | Class | Purpose | Interest Rate | Price | Per Cent Yield |
|---|---|---|---|---|---|---|---|
| American Gas & Electric Co. | $50,000,000 | 100 | Gold debentures | To redeem bonds | 5 | 101 | 4.95 |
| New England Power Association | 25,000,000 | 20 | Gold debentures | To retire short-term bank loans and for the payment of other indebtedness | 5 | 100 | 5.00 |

## American & Foreign Power Acquires Mexican Properties

A plan has been consummated whereby the American & Foreign Power Company, Inc., will acquire the collateral gold bonds, preferred stock and common stock of the Mexican Utilities Company by giving its 6 per cent preferred stock in exchange for the other company's securities on the following basis:

For each $100 principal amount of the collateral gold bonds of the Mexican Utilities Company, nine-tenths of a share of the $6 preferred stock of the American & Foreign Power Company, Inc., with a cash adjustment of accrued interest.

For each share of the preferred stock of the Mexican Utilities Company, 75-100ths of a share of the $6 preferred stock of the American & Foreign Power Company, Inc., with a cash adjustment of accrued dividends.

For each share of the common stock of the Mexican Utilities Co., 35-100ths of a share of the $6 preferred stock of the American & Foreign Power Company, Inc.

The privilege of exchange is extended to all holders of collateral gold bonds, preferred stock and common stock now outstanding of the Mexican Utilities Company who shall avail themselves thereof by depositing their holdings on or before June 1, 1928, or on or before any extended date. The American Exchange Irving Trust Company, 60 Broadway, New York, is depositary under the plan.

The Mexican Utilities Company is a holding company organized three years ago in Maine.

## General Gas & Electric System Net Income Up 8 per Cent

By a reduction of about 4 per cent in operating expenses, taxes and maintenance the officers of the General Gas & Electric group succeeded in showing an 8 per cent growth in net revenue, although gross revenue increased less than 2 per cent during 1927. Details of financial operations covering its large-scale hydro-electric development near Columbia, S. C., will be given in a later issue.

INTERNATIONAL POWER STOCK. — Shareholders of the International Power Securities Corporation at their recent annual meeting approved an increase in authorized common stock from 350,000 to 1,000,000 no-par shares.

## New Capital Issues

During the week ended May 10 the Southern Cities Utilities Company made an offering of 30-year 5 per cent first lien and collateral trust gold bonds, series A, to the amount of $10,500,000, the price being 94 and accrued interest, to yield 5.40 per cent.

The Rumford Falls Power Company (Maine) issued general mortgage 4½ per cent gold bonds to the amount of $2,000,000 at 98½ and accrued interest, to yield over 4.60 per cent. These bonds mature May 1, 1948.

The American Power & Light Company issued 200,000 shares of $5 preferred stock, series A, stamped certificates at $95 a share plus an amount equal to accrued dividends at the rate of $5 per share per annum from April 1, 1928, to yield 5.25 per cent.

With the purpose of retiring 7 per cent prior preference stock the Puget Sound Power & Light Company issued 110,000 shares of $5 dividend prior preference stock at 96 and accrued dividend, to yield 5.20 per cent.

One foreign offering was made—a three-and-a-half-million-dollar issue of

sinking fund mortgage gold bonds of the Pomerania Electric Company, which serves the Prussian Province of Pomerania as well as portions of adjoining provinces. The bonds, dated May 1, 1928, and maturing May 1, 1953, were priced at 92½ and interest, yielding over 6.60 per cent.

## Customer-Ownership Sales

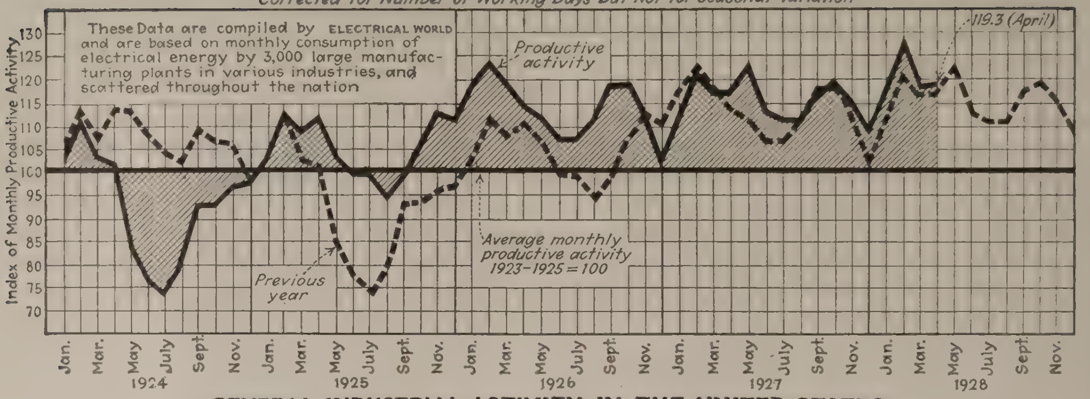
Somewhat less than average activity in customer-ownership campaigns is reflected in the reports of sales for January, and a further reduction occurred in February. In the former month the total value amounted to $16,171,029, the number of shares sold was 281,167 and the transactions 21,351. February sales of 154,306 shares, valued at $8,856,012, were made in 15,930 transactions.

January sales were virtually equal in value to those of December, and exceeded those of the four lowest months in the second half of 1927, but were in turn exceeded in October and November. February sales were somewhat below those of August, the last previous low month. The average amount per transaction was $760 in January and $555 in February. Neither of these figures is exceptional. These sales, in the nature of the case, fluctuate widely from month to month. It is of interest, though, that in January nine companies reported sales aggregating $500,000; in February there were only four.

LOUISVILLE GAS STOCK CHANGES.—Louisville Gas & Electric shareholders will consider at their annual meeting, May 18, a recommendation that class A stock be made non-callable and classes A and B share equally in any dividends declared after the payment of quarterly dividends at the rate of $1.50 a share on both stocks.

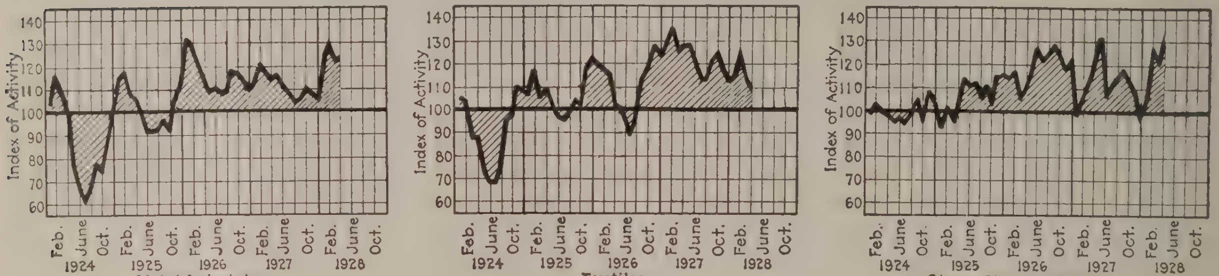
GENERAL ELECTRIC ELECTS NEW DIRECTOR.—Henry C. McEldowney, president of the Union Savings Bank and Union Trust Company, both of Pittsburgh, was elected a director of the General Electric Company at the organization meeting of the board held May 8 at Schenectady. The stockholders of the company at their annual meeting authorized the additional director, increasing the total from twenty to twenty-one. Other directors were reelected. Mr. McEldowney is a director of the Mellon National Bank of Pittsburgh and of the Pittsburgh Chamber of Commerce.

Corrected for Number of Working Days But Not for Seasonal Variation



These Data are compiled by ELECTRICAL WORLD and are based on monthly consumption of electrical energy by 3,000 large manufacturing plants in various industries, and scattered throughout the nation

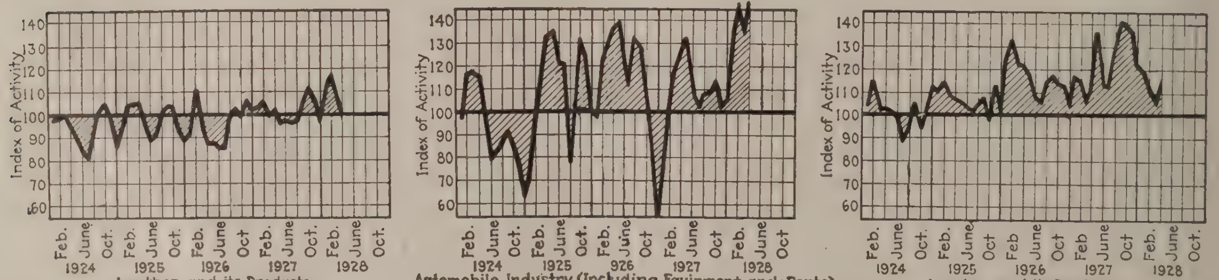
GENERAL INDUSTRIAL ACTIVITY IN THE UNITED STATES



Metal Industries

Textiles

Stone, Clay, and Glass



Leather and its Products

Automobile Industry (Including Equipment and Parts)

Lumber and its Products

PRODUCTIVE ACTIVITY IN THE PRIMARY INDUSTRIES OF THE UNITED STATES

# Increased Productive Activity in April

THAT the present general optimism in business and industry which is prevalent in most sections of the nation is but a reflection of the individual operations is indicated by the consumption of electrical energy. Reports of energy consumption in April made to ELECTRICAL WORLD by some 3,000 large manufacturing companies reveal that the rate of industrial production in the first month of the second quarter of the year was close to 1 per cent greater than that witnessed in March and about 2.2 per cent over April of last year. Industrial operations are being well sustained, some of the outstanding industrial groups recording increased operations, when a slight seasonal decrease would be expected normally. The favorable industrial situation is reflected by the fact that during the first four months of the current year the average rate of activity of general industry was about 3.7 per cent above that during the same period in 1927.

The index of activity in general industry based on consumption of electrical energy stands at 119.3 for April, as compared with 118.2 in March. Comparative indexes of productive activity referred to the average activity for the period 1923-25 as 100 and adjusted for number of working days are as follows:

| | |
|---|---|
| April, 1928 | 119.3 |
| March, 1928 | 118.2 |
| April, 1927 | 116.9 |
| Average first four months 1928 | 120.9 |
| Average first four months 1927 | 116.5 |

The most favorable aspects of the general industrial situation are to be found in the operations of the metal-working plants, the automobile manufacturing industry, which is but a branch of the metal-working industry, and in the stone, clay and glass industrial group. The ferrous and non-ferrous metal working plants reported a 3.5 per cent increase in operations during April and are operating on a plane about 14 per cent above last year. The automobile manufacturing plants, including replacement parts production, reported a 9 per cent increase during April over March, or at a rate 17 per cent above April last year. The stone, clay and glass group was up 10.3 per cent over March, or 14 per cent above April, 1927. On the unfavorable side must be placed the textiles industry, which reported a material drop in rate of operations during April, to a rate almost 15 per cent under April last year. The paper and pulp mills reported operations about 3 per cent under those of the month of April, 1927.

---

HYDRO-ELECTRIC SECURITIES OFFICERS.—New officials of this corporation include Sir Herbert Holt, chairman of the board, and Alfred Loewenstein, president. The board will include as new members J. H. Gundy, S. Godin, Jr., and Prentiss N. Gray. According to Mr. Loewenstein the corporation will shortly have a capital of about $57,000,000, as well as $30,000,000 of unsold preference A stock and about 500,000 common shares, which may be issued when the opportunity arises.

# Business News and Market Conditions

## Electric Truck Industry Holds Conference in Chicago

The electric truck industry, composed of representatives of the transportation committee, Commercial National Section, N.E.L.A., its truck operation subcommittee, the electric street and industrial truck manufacturers' committees of the Society for Electrical Development, and the Electric Transportation Club of Chicago, met in a successful conference in Chicago recently. One all-day session was devoted to market development possibilities and sales programs were discussed. The purpose of the conference, which was to bring the truck manufacturers and the power companies more closely together in the common problem of promoting electric transportation, was outlined by John F. Gilchrist, vice-president of the Commonwealth Edison Company. Reports on the status of the use of electric street and industrial trucks and plans for market broadening were presented by the following committee chairmen: L. M. Branch, Commonwealth Edison Company; F. H. Tinsley, Walker Vehicle Company; C. B. Cook, Ellwell Parker Electric Company, and G. E. Stringfellow, Edison Storage Battery Company.

A practical plan for central-station co-operation in the promotion of electric transportation was described by L. J. Lamberger, Duquesne Light Company, Pittsburgh, Pa., which company has recently created a special division in its sales department for this work. The central station and its relation to electric truck promotion in other cities was

### DESTINATION OF ELECTRICAL EXPORTS

| Country of Destination | February, 1928 |
|---|---|
| EUROPE: | $1,764,912 |
| Belgium | 107,935 |
| France | 161,501 |
| Germany | 126,369 |
| Italy | 105,266 |
| Netherlands | 79,431 |
| Spain | 325,709 |
| Sweden | 27,241 |
| United Kingdom | 511,968 |
| Other countries | 319,492 |
| WESTERN HEMISPHERE: | $4,330,290 |
| Canada | 1,729,690 |
| Mexico | 439,968 |
| Cuba | 240,678 |
| Argentina | 467,663 |
| Brazil | 475,674 |
| Chile | 244,589 |
| Colombia | 215,974 |
| Peru | 56,556 |
| Venezuela | 98,393 |
| Other countries | 361,105 |
| ASIA, AFRICA AND OCEANIA: | $171,940 |
| British India | 139,643 |
| China | 109,662 |
| Japan | 353,899 |
| Philippine Islands | 134,217 |
| Australia | 443,167 |
| New Zealand | 146,306 |
| Union of South Africa | 91,457 |
| Other countries | 353,589 |

outlined by C. R. Skinner, New York Edison Company; F. E. Nelson, Indianapolis Power & Light Company; H. S. Greiner, Minneapolis General Electric Company; F. S. Dewey, Kansas City Power & Light Company; E. L. Huston, Union Gas & Electric Company, Cincinnati, and D. F. Estes, Commonwealth Edison Company, Chicago.

Use and application of electric trucks for utility transportation problems were discussed by A. H. Gossard, Middle West Utilities Company; Secor Cunningham, Commonwealth Edison Company; H. P. Sedwick, Public Service Company of Northern Illinois, and J. R. Coxen, Consolidated Gas Company. On Friday the conference was given over to inspection of the use of electric trucks by the Commonwealth Edison Company and various industrial installations in Chicago. Sixty-eight representatives of the electric truck industry and utility companies attended the conference and it was felt that through the conference a new impetus had been given to the promotion of electric street and industrial truck transportation.

# Market Conditions

MATERIAL for extending service lines makes up an important part of the business in New England. Orders are mainly in small lots with the activity general. Industrial equipment buying is limited to small motor orders, of which a fair volume is maintained. In the Eastern district there is an increasing demand for industrial equipment. Transportation companies are looming up as an important factor in the electrical business. A New York utility company has ordered $70,000 worth of paper-insulated cable and $30,000 worth of substation apparatus. A company in northern New York also purchased $30,000 worth of switching equipment.

Continued rains have delayed construction work and crop planting in the Southeast, but business is satisfactory, although there is some pessimism in the rural sections. A slight improvement is recorded in the St. Louis district and there has been a marked improvement in the demand for medium-sized motors. A great deal of underground construction work is under way in the Middle West as well as a considerable amount of building, particularly larger structures. On the Pacific Coast varied machinery orders were placed. Lumber mills in the Puget Sound district are working on a five-day week.

## *Copper Price Strengthens—Sales Excellent*

Copper sellers did an excellent business with virtually all of it being done on the basis of 14.25 cents Connecticut. Zinc, though not particularly active, has commanded better prices and 6 cents has been realized on several sales for future delivery. Lead and tin have both been quiet and occasional shading of the prices for lead that have prevailed for some weeks is reported. Tin sagged slightly but was a little firmer on Wednesday.

NEW YORK METAL MARKET PRICES

| | May 2, 1928 Cents per Pound | May 9, 1928 Cents per Pound |
|---|---|---|
| Copper, electrolytic.... | 14.025 | 14.025–14.05 |
| Lead, Am. S. & R. price | 6.10 | 6.10 |
| Antimony............ | 10.375 | 11¼ |
| Nickel, ingot.......... | 35.00 | 35 |
| Zinc spots............ | 6.225 | 6.325 |
| Tin, Straits........... | 51⅜ | 51.875 |
| Aluminum, 99 per cent | 24.30 | 24.30 |

Base copper wire price May 9, 1928, 16 cents.

## *Service Expansion Promotes New England Sales*

Extension of service lines throughout New England is promoting sales. Buying of poles, wire, disconnecting switches and control equipment is recorded. Orders for small lots dominate the tone, among which are noted material for southern New Hampshire amounting to about $2,000. An order for disconnecting switches and accessories, amounting to $3,000, for a prominent power company and a number of insulator orders ranging from 200 to 1,000 lots were reported. A distributor reports that the general tone of business is steady and last month's sales were encouraging. New work centers about a number of line extensions planned for central and northern Maine, bids for which will be received soon.

Industrial equipment buying is limited to small motor orders, of which a fair volume is maintained. A few of the larger ratings up to 50 hp. are in demand and a number of loom motors were recently purchased. Heavy equipment buying is lagging, and negotiations are quiet. Special equipment is attracting attention. One company recently placed twelve motor-driven woodworking machines in a well-known institute. Small heating furnaces also are receiving attention. Appliance sales are steady and outdoor electric lighting and display signs are being promoted through special campaigns. Construction projects are as follows:

The Connecticut Light & Power Company, Waterbury, Conn., plans a repair and distributing plant to cost $200,000. The Baird Machine Company, Stratford, Conn., plans an addition to cost $85,000. The Boston Elevated Railway, Boston, plans a substation on Warren Street to cost $40,000. The Boston & Maine Railroad will make improvements in the car repair shops at Keene, N. H., to cost $175,000. Chicopee Center, Williamsett and Aldenville, Mass., plan ornamental lighting systems.

## *Industrial Business Better in Middle West*

Reports from agricultural districts in the Middle West are encouraging and industrial activity has accelerated somewhat. A considerable amount of building is under way, particularly larger structures. The utility companies are extremely busy, and a great deal of underground construction work is being done. Interesting orders include one for 250 distribution transformers in assorted sizes, one 55,000-kw. reheat turbine generator complete with appurtenances, 50,000 lb. copper bus bar, a quantity of disconnecting switches, circuit breakers and relays, and several construction orders totaling $50,000. Jobbers' sales are somewhat spotty. Considerable business is being obtained from railroad and municipal sources. Construction plans are as follows:

The Container Corporation of America, Chicago, plans a paper board mill to cost $300,000. The Chevrolet Motor Company plans an addition to its power plant at Detroit, Mich., to cost $100,000. The Patterson Foundry & Machine Company, East Liverpool, Ohio, plans an addition to cost $100,000. The Wisconsin Power & Light Company, Madison, Wis., plans a power plant on Yellow River, near Necedah, Wis., to cost $250,000. Emmetsburg and Indianola, Iowa, and Marquette, Mich., plan ornamental lighting systems.

## *Rains Delay Construction in Southeast—Sales Fair*

Despite continued rains which have delayed construction and considerably delayed the planting of crops, which latter fact is causing some pessimism in the rural sections, conditions in the Southeast are healthy and the volume of electrical business is satisfactory. A Tennessee company ordered copper wire and cable amounting to $5,000 and another company in the same state purchased power transformers aggregating $5,000. Another order for small power transformers came from a Georgia company and amounted to $4,000. Some other central-station orders included $5,000 worth of insulators and $3,300 worth of small switching equipment.

A silk mill under construction in Tennessee ordered copper wire and cable amounting to $15,000, and substation equipment amounting to approximately $10,000 for a rock quarry in Georgia will be ordered in the very near future. A new cement mill will be constructed in Georgia and material contracts will soon be let. Approximately $90,000 of motors, switchboard, transformers and wiring materials will go into that job. Construction projects are as follows:

The South Georgia Power Company, Albany, Ga., has purchased the municipal system in Rochelle and will connect with a transmission line. The Marianna Lime Products Company, Marianna, Fla., plans a cement mill at White Cliffs, Ark., to cost $500,000. The Shellabarger Mill & Elevator Company, Salina, Kan., will build a grain elevator to cost $350,000. The Kemper Military School, Boonville, Mo., plans an addition to its power plant. Swift & Company, Chicago, will install a cold storage plant at St. Louis to cost $400,000. Frederick E. Kern, Syndicate Trust Building, St. Louis, and associates, plan a fire brick and refractory plant, to cost $350,000.

The Laclede Power & Light Company, St. Louis, plans a switching station at Mound Street to cost $40,000. Anheuser-Busch, Inc., St. Louis, plans extensions in its power plant to cost $200,000. The Union Electric Light & Power Company, St. Louis, plans a substation on Clark Street to cost $45,000. The Dry Kold Products Company, 69 Neron Place, New Orleans, La., plans plants at Dallas and other points in Texas and Louisiana to cost $1,000,000. The Hahn Packing Company, Dallas, Tex., plans a rendering and packing plant to cost $100,000. Vernon, Tex., will build a power plant to cost $25,000. Brownsville, Tex., will build a substation, to cost $22,000. Houston, Tex., plans an improved lighting system on a number of streets.

## *Industrial Plants Buying in Eastern District*

Increasing demand for electrical equipment for industrial service is a feature of the market in the Eastern district. A recently organized rayon company will soon place orders for a considerable quantity of equipment for a $4,000,000 mill in Georgia. A nitrogen company in northern New York has contracted for industrial heating equipment to cost about $25,000. A steel chain manufacturing plant at Albany will make purchases for a new mill unit to cost close to $500,000.

Transportation account looms as an important consumer within a short time; New York will soon ask bids for equipment for two specimen subway trains of improved type, and a steam railroad has placed an order for parts, for reconditioning electric locomotives, to cost $40,000, and a contract for air compressors to cost $30,000. The electrification of the New York west side lines of the New York Central Railroad is scheduled to proceed at an early date, the cost to aggregate several million dollars and other New York Central plans are being rumored; plans for electrification of suburban lines of the Lackawanna Railroad, to cost $15,000,000, will soon be issued, and manufacturers are awaiting an opportunity to quote on requirements. The Reading Company, Philadelphia, also will make purchases for its $20,000,000 electrification program.

Central-station account is growing inactive in the Eastern district and the bulk of present business centers in miscellaneous and auxiliary apparatus. A New York utility has contracted for paper-insulated cable to cost $70,000, also for switches and protectors for substation service to cost about $30,000. A power company in Northern New York has placed a commitment for switching and accessory equipment to cost about $30,000. A new Jersey central station has been making purchases of transformers and other substation apparatus for several sizable projects and is expected to give additional contracts at an early date. A leading manufacturer of waterwheels states that current business for impulse type units is lower than that of a year ago at this time, owing largely to the falling off in demand on the Pacific Coast. Export sales of waterwheels are improving, with South American utilities prominent in the market. Construction activities in the Eastern district are as follows:

The New York Edison Company plans a substation to cost $450,000. The Ramsey Chain Company, Albany, N. Y., plans a plant to cost $500,000. The Liberty Construction Stone Company, New York, will build a plant to cost $100,000. The Eastern States Milling Corporation, Buffalo, N. Y., plans a grain mill to cost $200,000. The Oswego Candy Company, Oswego, N. Y., plans a factory addition to cost $100,000. The American Chatillon Company, New York, plans a new rayon mill at Rome, Ga., to cost $4,000,000.

The Gates-Day Aircraft Corporation, Paterson, N. J., will build a plant to cost $100,000. The Public Service Electric & Gas Company, Newark, N. J., plans a substation at Camden, N. J., to cost $500,000. The Anti-Hydro Waterproofing Company, Newark, N. J., will build an addition to cost about $100,000. The Philadelphia Rapid Transit Company, Philadelphia, plans a motor bus repair shop to cost $250,000. E. H. Reuss, Jr., Philadelphia, plans a pipe-bending and manufacturing plant to cost $200,000. The Bethlehem Shipbuilding Corporation, Baltimore, Md., will build a second unit to cost $500,000.

## *Varied Machinery Orders Placed on Pacific Coast*

Many interesting and varied machinery orders are reported on the Pacific Coast. They include 96 distribution transformers and a lot of lightning arresters and insulators having a total value of $15,000 for the Truckee Carson irrigation project, six 100-kva. subway transformers, valued at $5,000, for Pantages theatre, Fresno, thirteen assorted induction motors, valued at $2,500, for a Hawaiian sugar plantation, one carload assorted pin-type insulators, valued at $6,000, for a manufacturer of outdoor switches, one carload 11,000-volt pin-type insulators, valued at $6,500, for San Joaquin Valley extensions, 20 assorted motors, valued at $6,000, for a Bay district industrial plant and 200 transformers for power company stocks.

Lumber mills in the Puget Sound country, affiliated with the West Coast Lumbermen's Association, have agreed upon a curtailment program providing for a five-day week operation for an indefinite period. Previous to this action, several large mills in the Grays Harbor district closed down voluntarily and large mills in Tacoma abolished night shifts. The Weyerhaeuser Timber Company, Longview, Wash., is expected to award contracts in a few days for turbines and other equipment. Sales reported include about $10,000 worth of switchgear to a central-station company in Thurston county, ten 25-hp. motors for a Seattle can company and about fifty motors to lumber mills and allied industrials. Construction plans in the district are:

The San Francisco Produce & Provision Terminals, Inc., San Francisco, plans a warehouse and cold storage plant to cost $2,500,000. The Security Warehouse & Cold Storage Company, Santa Clara, Calif., plans a cold storage plant, to cost $150,000. The Empire Zinc Company, Belden, Colo., plans a milling plant to cost $250,000. The Black Hawk Consolidated Mines Company, Silver City, N. M., will build a milling plant to cost $100,000. The Oregon-Washington Railroad & Navigation Company, Portland, Ore., will make additions in its car and locomotive shops to cost $133,000.

The Wyoming Carbonizing & Briquetting Company, Kemmerer, Wyo., plans a new plant at Conroy, Wyo., to cost $150,000. The Western Public Service Company, Colorado Springs, Colo., plans additions to its power plant at Laramie, Wyo., to cost $76,000. The Public Service Company of Colorado, Denver, plans extension in transmission lines and distributing system at Alamosa, Colo., and vicinity. The Bureau of Reclamation, Denver, Colo., will receive bids until May 25 for construction of 19.1 miles, 66,000-volt, single-circuit wood pole, transmission line, and 13 miles single-circuit telephone line, near Adrian and Nyssa, Ore. Madera, San Jose, North Hollywood, Berkeley, San Diego, Santa Paula, Long Beach and Los Angeles, Calif., plan ornamental lighting systems.

## *Slight Improvement Recorded in St. Louis District*

Conditions show a slight improvement in the St. Louis district. There has been a marked increase in the demand for medium-sized motors and transformers, also meters and lightning arresters. One order, including 2,000 kva. of transformers with substation equipment amounted to $16,000 and was for use in the Southwest. Manufacturers report a good volume of business in domestic and heavy-duty ranges. One contract for a baking oven to cost $2,000 was placed. An order for a bank of transformers was placed by an industrial company at a cost of $2,500. The southern part of the district has shown the greatest activity of late. Construction activities are as follows:

The Bemis Brothers Bag Company, St. Louis, plans a cotton mill near Talladega, Ala., to cost $1,500,000. The Florida Power Corporation, Ocala, Fla., plans a Diesel engine power plant at Mayo, Fla., to cost $100,000. The Inland Utilities Company, Kansas City, Mo., plans a power plant at Blue Mountain, Miss., to cost $75,000. The Southern Fruit Company, Inc., Charlotte, N. C., plans a cold storage plant to cost $100,000. The Airial Mill, Easley, S. C., will build a cotton mill to cost $150,000. The Gaffney Manufacturing Company, Gaffney, S. C., will build an addition to its textile mill to cost $200,000.

The Sani-Fold Corporation, Athens, Tenn., plans a furniture plant to cost $200,000. Cookeville, Tenn., plans extensions in its power plant to cost $150,000. The Arrington Cold Storage Corporation, Arrington, Va., will build a cold storage plant to cost $100,000. The Mississippi Power Company, Gulfport, Miss., is negotiating for the purchase of the municipal plant at Flora, Miss. The Mississippi Power & Light Company, Pine Bluffs, Ark., has acquired the municipal plant at Summit, Miss. Palmetto, Fla., and Richmond, Va., plan improved street lighting systems.

# Activities of the Trade

## Landers, Frary & Clark Celebrate 75th Anniversary

To celebrate its 75th anniversary in its corporate form Landers, Frary & Clark of New Britain, Conn., manufacturer of electric appliances, household hardware, etc., are offering to dealers during the month of May a special 10 per cent price reduction on all urns and percolators. The company, in a letter to its dealers, states: "In preparation for this May sale your regular source of supply will ship you one order of nickeled or silver 'Universal' electric urns or percolators separately or in sets with accessories at 10 per cent below your usual cost. This is in expectation that these specially priced goods will be offered to consumers at 10 per cent savings during the month of May only."

The Wagner Electric Corporation, St. Louis, announces the removal of its New York City branch sales office from 50 Church Street to 30 Church Street, Suite 1110. The New York City service station remains at 321 West 54th Street.

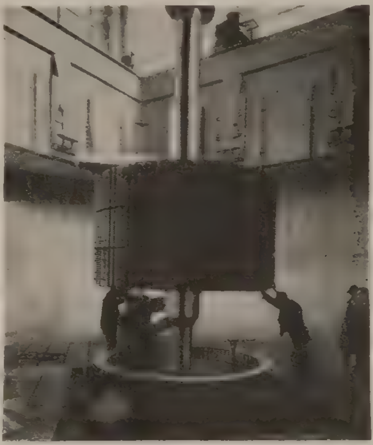
The General Electric Company announces the appointment of A. L. Jones as district manager in the Rocky Mountain region, with headquarters at Denver. Mr. Jones will supervise the sales in the nine states of the region with sub-offices at Butte, Mont., and Salt Lake City, Utah.

The Perfection Appliance Company, Detroit, manufacturer of the Perfection electric ironer, a division of the Splitdorf-Bethlehem Electrical Company of Newark, N. J., announces that A. H. Graham, formerly campaign manager for the Servel Corporation in the Southeastern division, has joined its sales organization as special sales representative working out of the head office in Detroit.

The Dampney Company of America, Hyde Park, Boston, Mass., announces that the sale of its "Apexior" protective coatings for power plant equipment will be handled in Colorado, western Nebraska, eastern Wyoming and northern New Mexico by Joy & Cox Inc., 314 Tramway Building, Denver.

The Lincoln Electric Company, Cleveland, manufacturer of "Linc-Weld" motors and "Stable-Arc" welders, announces the following changes and additions to its sales and welder service divisions. H. A. Stamper has been placed in charge of consumer motor sales and D. F. Titus in charge of welder service in the New York district under the direction of G. N. Gull, district sales manager; A. H. Kirkpatrick replaces D. W. Carver as manager of welder service in the Cincinnati district under M. R. Simpson, Mr. Carver having been transferred to the Cleveland district; H. E. Nelson will take charge of the consumer motor sales in the Cincinnati district; P. A. Ludwig has assumed charge of the welder service in Philadelphia and vicinity; Forrest Kessler has been transferred to the welder service division in the Cleveland district and J. R. Rothermel is in charge of welder service at Chicago under R. D. Malm, district manager, while W. Weaver has been placed in charge of the consumer motor sales in the Chicago district.

## Overspeed Tests Made Safely in General Electric Test Pit



Lowering a 30,000-kw. waterwheel generator rotor into the new General Electric test pit.

The Electric Service Supplies Company, Seventeenth and Cambria Streets, Philadelphia, manufacturer of railway and power electrical material, announces the removal of its Chicago offices and warehouses to larger quarters at 111 North Canal Street, between Washington and Randolph Streets, directly opposite the Chicago & Northwestern depot.

The Cutler-Hammer Manufacturing Company, Milwaukee, manufacturer of electric controlling devices, announces a new toggle auto switch, designed to meet the severe requirements of truck and bus service.

The Crawford Oven Company, New Haven, Conn., announces that Robert M. Gantert, formerly associated with the Philadelphia Electric Company in developing bakery applications of electric ovens, has joined its sales organization. He will devote his time helping bakeries and food-products manufacturers in southeastern New York, New Jersey, Pennsylvania, Delaware, Maryland and the District of Columbia solve their oven problems. The Crawford Oven Company manufactures a complete line of traveling ovens for baking and industrial applications. The company, at an early date, intends to open an office in New York City in charge of Mr. Gantert.

The Trico Fuse Manufacturing Company, Milwaukee, announces the removal of its Pittsburgh office to new and larger quarters at 405 Penn Avenue, in charge of W. A. Bittner.

The Oliver Iron & Steel Corporation, Pittsburgh, announces the appointment of Nelson G. Craig as district manager at 1420 Walnut Street, Philadelphia. Mr. Craig will have charge of the bolt, nut, rivet and pole line material sales in the Philadelphia territory.

The Electric Furniture Corporation and affiliated associated companies announce the opening of new showrooms in the St. Clair Building, Chicago, centrally located near the furniture mart. The Electric Furniture division has developed several distinct types of furniture equipped with a patented "Utilitap," a three-outlet tap mounted flush with the surface of the woodwork.

The General Electric Company, merchandise department, Bridgeport, Conn., announces that it is now marketing a line of "Textolite" attachment plugs.

Pass & Seymour, Inc., Solvay Station, Syracuse, N. Y., has placed on the market an intermediate base line of sockets and receptacles.

The Oliver Iron & Steel Company, Pittsburgh, announces that Bertram Quarrie has been elected president of the company to succeed Henry Oliver, who has become chairman of the board of directors. Mr. Quarrie was formerly connected with the American Steel & Wire Company and the Otis Steel Company at Cleveland. This corrects an item appearing in the April 21 issue of the Electrical World in which it was stated that Mr. Oliver had resigned from the company.

The Yale Electric Corporation, Pearl and Tillary Streets, Brooklyn, N. Y., manufacturer of flashlights and dry batteries, announces that the company is now established in its new million-dollar building at 257 Cornelison Avenue, Jersey City, N. J.

The American Electric Switch Corporation, Minerva, Ohio, announces that it has added another building to its factory. The new building comprises two floors and a basement and has a floor space of 26,000 sq.ft. The switchboard, panelboard, knife switch and shipping departments will occupy the new addition.

The Hynes & Cox Electric Corporation, 406 North Pearl Street, Albany, N. Y., manufacturer of "Red Crown" water heaters, announces that it is now manufacturing the "Duostat" automatic electric water heater. This is a low wattage storage type heater using two heating elements, each of which is controlled by its own thermostat.

The Timken Roller Bearing Company, Canton Ohio, announces that W. H. Post has been appointed manager of the Pittsburgh branch of the service and sales divisions.

The Erie Malleable Iron Company, Erie, Pa., announces that since May 1 C. E. Collier has been in charge of its Western office, with headquarters at 911 Peoples Gas Building, Chicago, succeeding C. E. Callender, who has resigned.

The G-Q Electric Company, 208 Broadway, Milwaukee, jobber, announces the opening of a branch office at 531 West College Avenue, Appleton, Wis., which will serve the Fox River Valley.

# New Equipment Available

## High-Voltage Disconnect Switches

A line of group-operated disconnect switches for outdoor service in capacities of 600 and 800 amp. and voltages from 132,000 to 220,000 has been developed by the General Electric Company. These switches, which are intended for isolating oil circuit breakers on high-voltage, super-power systems, have short, fixed blades on insulators suspended from trucks. The trucks are moved backward or forward on ship channel frames. The stationary contacts are assembled on insulators suspended at the extreme ends of the frames. The contacts are of the spring-pressure line-contact type.

The manufacturer claims that this design permits a considerable saving in space over other types of switches using long swing blades. These switches are built in six-pole, single-throw and three-pole, single-throw types and carry the designations HD-1 and HD-2, respectively. Either manual or motor operation may be provided.

## Fractional-Horsepower Direct-Current Motors

A line of fractional-horsepower direct-current motors in standard sizes from 1/6 hp. to $\frac{1}{2}$ hp. at speeds corresponding to standard speeds of alternating-current motors has been placed on the market by the Century Electric Company, St. Louis. The field is a two-pole laminated steel structure. The compound-wound field coils are wound on forms, well insulated and taped. The armature slots are insulated with alternate layers of fish paper and varnished cambric. Hardwood wedges are used to retain the coils. Both field and armature coils are wound with cotton-enamel wire and thoroughly treated with insulating paints to withstand the dampness frequently surrounding installations in basements and humid tropical climates.

The bearings are made of cast phosphor bronze. The Century wool-yarn system of lubrication is used. The commutator, which is said to be of liberal size, is made from rolled copper bars and insulated with mica. The brushes are carried in a box-type brush-holder attached to the field frame and do not require adjustment during the life of the brushes.

## Lift-Truck for Heavy Reels

A storage battery lift-truck designed especially for handling reels of wire or cable has been developed by the Lakewood Engineering Company, Cleveland. The truck has a capacity of 6,000 lb. and will handle reels up to 60 in. in diameter and 42 in. wide. The winches, which operate on a bar placed in the center of the cable reel, slide upward on the trunnions and wind in at the same time thus securing a double action.

Guide Clamp.—A guide clamp which will prevent a conductor breaking as the result of crystallization close to the point where it is rigidly held to the connection member of an oil circuit breaker, transformer, or disconnecting switch has been placed on the market by the General Electric Company. The new guide clamp consists of a cast arm 4 to 6 in. long, provided with holes at each extremity for bolting to the conductor and terminal. Its function is to distribute the point of flexure over an appreciable length of conductor and thus to relieve the metal adjacent to the connecting stud of the full effect of vibration and swinging which often results in crystallization and ultimate failure. The clamp is made in a variety of sizes suitable for attachment to conductors in sizes from No. 2 up to $2\frac{1}{2}$-in. iron pipe size copper tubing.

Tension Indicator.—A tension indicator for determining tension in guy wires, messengers and line conductors has been placed on the market by the Martin-Loomis Corporation, Long Beach, Calif. The device is designed for use on wire from $\frac{1}{4}$ in. to $1\frac{1}{4}$ in. in diameter. It is not a dead-end instrument and can be installed on any line, either before or after tension is applied. Two rigid clamps on the main body 9 in. apart, through which the wire passes, are so made that the clamps swing to allow attachment to a line under tension. The tendency of the wire to resist being deflected between the two clamps exerts a pressure on a diaphram which is registered on a pressure gage. The instrument weighs only 12 lb.

## Automatic Telemetering Device

An automatic telemetering device, recently placed on the market by the General Electric Company, covers the readings of meters and instruments in all parts of the power system, and indicates or records them on a single receiving apparatus located at some central point, such as the load dispatcher's office. The telemetering system operates over a single pair of wires, the receiver being actuated by impulses sent out by relays associated with the outlying meters. Since the readings are transmitted by impulses, ordinary variations in line wire resistance or battery voltages have no effect on the accuracy of the telemetering. Carrier current channels may be used to transmit the readings, and in cases telephone circuits may be employed, without imparing communication in any way. Where a large number of intermittent readings from a particular station are required, standard supervisory equipment is utilized.

The telemeter proper, located at the load dispatcher's headquarters, is an accurate speedometer calibrated in terms of the speed of the rotating meters at the sending end. It consists essentially of a motor connected by a spring coupling and gearing to a permanent magnet. The motor is allowed to make one revolution for each impulse received. This is transferred to the permanent magnet by means of a flexible spring coupling and gearing. Hence the magnet also makes a definite portion of a revolution for each impulse received. The dragging effect of the revolving magnet upon a disc, to which the dial hand or recording pen is attached, translates the impulses into readings proportional to the indication of the outlying meter.

Important readings such as voltage, amperes, kilowatts, reactive kilovolt-amperes, and frequency, may be transmitted in this manner from all parts of the system. The dispatcher may have either visual or recording equipment for receiving them. When kilowatts are transmitted, each impulse represents a definite number of kilowatt-hours. The telemetering device may therefore operate a demand meter or register kilowatt-hours on a dial. Kilowatts from several remote points may be totalized on one receiving meter.

Device for Locating Defects in Machinery.—The "Transmit-o-phone" for locating defects in power plant machinery, motors, etc., and for locating leaks in pipe lines, hidden conduits or pipes, etc., has been placed on the market by the International Metal & Specialty Company, Berlin, N. J. The instrument has a variety of applications. It has been used to locate flooded conduits as well as to determine the exact cause and origin of the flooded conditions. The instrument is essentially a sensitive sound detecting device. The manufacturer also claims that the instrument can be used to locate defective electric meters.

# Electrical Patents

*Announced by U. S. Patent Office*

(Issued April 24, 1928)

16,940 (reissue). Thermostat; R. F. Massa, New York, N. Y. App. filed Nov. 11, 1913.

1,666,889. Transformer; J. Desloge, St. Louis, Mo. App. filed March 30, 1925. Bell-ringing type.

1,666,897. Ship-Guidance System; J. H. Hammond, Jr., Gloucester, Mass. App. filed April 27, 1922. For indicating the relative positions of movable bodies whereby desired relative positions may be maintained.

1,666,904. Time Switch; R. D. Mailey, East Orange, N. J. App. filed Oct. 30, 1923. Mercury type.

1,666,916. Electrically-Operated Door; H. Rowntree, Scarsdale, N. Y. App. filed Oct. 4, 1924.

1,666,923. Protective Device; W. W. Woodruff, Swarthmore, Pa. App. filed Nov. 3, 1922. Fusible cutout.

1,666,925. Switch Construction; R. B. Benjamin, Chicago, and C. E. Warner, Berwyn, Ill. App. filed Nov. 5, 1923. Toggle type.

1,666,970. Electromagnet; C. L. Jauss, Mexico, Mex. App. filed Sept. 23, 1925. Especially designed for the operation of locks.

1,666,973, 1,666,974. Double-Contact Socket for Electric Lamps; F. J. Miles and D. C. Thompson, Newark, N. J. Apps. filed Nov. 14, 1924. For use with small incandescent electric lamps.

1,666,978. Terminal Contact Clip; J. Sachs, Hartford, Conn. App. filed Dec. 12, 1921.

1,666,979. Fusible Switch; J. Sachs, Hartford, Conn. App. filed Jan. 25, 1923.

1,666,980. Cable Head; J. E. Sharp, Wheeling, W. Va. App. filed April 1, 1927. Head to be fastened over the eye in a steel snake with a view to enabling electricians to push the snake with facility through long stretches of conduit.

1,666,991. Electrical Connecter; S. Cohen, Neponsit, N. Y. App. filed Aug. 25, 1925.

1,667,018. Burglar-Alarm Mounting; P. V. Vandevelde, Corona, N. Y. App. filed April 13, 1926.

1,667,020. Pressure-Responsive Device; O. G. Wendel, Buffalo, N. Y. App. filed Sept. 21, 1921.

1,667,021. Translator of Electrical Energy; H. M. Williamson, Chicago, Ill. App. filed Dec. 8, 1923. Wherein electrical impulses are translated into audible sound waves or into physical vibrations.

1,667,025. Outlet-Box Hanger; C. E. Bowers, Los Angeles, Calif. App. filed Oct. 21, 1925.

1,667,035. Insulating Tube; P. A. Hünermann, Berlin-Weissensee, Germany. App. filed Sept. 28, 1926.

1,667,037. Electric-Circuit Closer; E. M. Kyle and E. F. Hurley, Lakeport, N. H. App. filed Dec. 1, 1924. For automatically closing a firm-alarm circuit.

1,667,056. Mercury-Contact Switch; I. E. Smith, Stockton, Calif. App. filed May 4, 1927.

1,667,070. Armature-Winding Machine; R. G. Jones, London, England, and C. Zwiebel, Dayton, Ohio. App. filed Jan. 23, 1925.

1,667,087. System of Electrical Transmission and Transformation; P. H. Thomas, Upper Montclair, N. J. App. filed Aug. 7, 1925.

1,667,142. Thermocouple; W. A. Darrah, Chicago, Ill. App. filed Feb. 24, 1925.

1,667,158. Electric Switch; C. E. Ives, Chicago, Ill. App. filed April 28, 1924. Hand operated switch embodied in a pistol grip or handle.

1,667,174. Oscillating Signal; R. R. Thompson, Los Angeles, Calif. App. filed Nov. 22, 1919. Railway signal.

1,667,178. Electrical Welding Apparatus; I. J. Van Huffel, Warren, Ohio. App. filed April 14, 1926.

1,667,242. Electric Converting Apparatus; J. E. Calverley, Preston, and W. E. Highfield, London, England. App. filed Nov. 12, 1925.

1,667,244. Electric-Welding Apparatus; A. Churchward, New York, N. Y. App. filed Nov. 8, 1926.

1,667,247. Electric Switch; J. J. Egan, Boston, Mass. App. filed March 25, 1926. For automatically cutting out an electrically heated flat-iron when the iron is turned upon its heel.

1,667,250. Electric Soldering Iron; W. Ensdorf, New York, N. Y., and J. Sandberg, Elizabeth, N. J. App. filed March 23, 1927.

1,667,257. Electric Heater; W. W. Hicks, San Francisco, and A. J. Kercher, Berkeley, Calif. App. filed Nov. 27, 1926. Adapted to prove a large area of contact between it and the medium to be heated.

1,667,293. Electric Switch; J. R. Marshall, McKean, Pa. App. filed June 5, 1925. Out-door switch.

1,667,297. Train-Line Coupler; H. E. Van Dorn, Chicago, Ill. App. filed May 9, 1921. For connecting together the electrical circuits on two adjacent railway cars.

1,667,308. Silent Secondary Clock; T. S. Casner, Plainfield, N. J. App. filed May 29, 1926. Electro-magnetically operated clock.

1,667,317. Dry Cell; G. W. Heise, Bayside, and H. H. Thompson, Flushing, N. Y. App. filed Nov. 18, 1922.

1,667,356. Time-Controlled Apparatus; C. M. Peacock, Oak Park, Ill. App. filed Aug. 29, 1925.

1,667,410. Speed-Responsive System; C. R. Beall, Swissvale, Pa. App. filed Sept. 5, 1923. Railway traffic-controlling apparatus.

1,667,418. Subaqueous Sound-Signaling Apparatus; W. Hahnemann, Kitseberg, near Kiel, and A. du Bois-Reymond, Plon, near Kiel, Germany. App. filed Feb. 4, 1921.

1,667,422. Demagnetizer; Toledo, Ohio. App. filed Nov. 13, 1920.

1,667,435. Lead Accumulator; R. Oppenheim, Levallois-Perret, France. App. filed April 18, 1925.

1,667,451. Apparatus for the Treatment of Organisms with Electrical Currents; W. T. Arnberg, Liljeholmen, Sweden. App. filed June 28, 1926.

1,667,452. Fishplate Bond; G. Barnes, Princeton, Ind. App. filed June 17, 1926.

1,667,469. Light Signal; P. E. Carter, Bronxville, N. Y. App. filed Nov. 9, 1921. Color light signals for railway signaling purposes.

1,667,485. Connecter; R. R. MacDonald, New York, N. Y. App. filed Aug. 25, 1927. For insulated stranded copper conductor cables.

1,667,487. Butt Welding; T. E. Murray, Jr., Brooklyn, N. Y. App. filed July 21, 1926.

1,667,510. Electric Conductor; J. R. Coe, Watertown, N. Y. App. filed July 30, 1924. A cable constituting an electrical conductor for high tension transmission lines having, in combination, a core comprising a plurality of short rigid members arranged end to end, and contacting wires of high electrical conductivity arranged spirally and side by side about the rigid members.

1,667,514. Synchronous Motor; V. A. Fynn, St. Louis, Mo. App. filed Nov. 26, 1923. Possessing mechanical features of induction motors and capable of carrying variable load at synchronous speed.

1,667,515. Plating Apparatus; F. P. Green, St. Louis, Mo. App. filed March 28, 1927.

1,667,521. Combined Gas and Electric Cook Stove or Range; F. C. Alber, Cleveland, Ohio. App. filed Nov. 26, 1924.

1,667,540. Method and Apparatus for Measuring Distance; H. G. Dorsey, Gloucester, Mass. App. filed Dec. 22, 1923.

1,667,555. Parkway-Cable Terminal; W. H. B. Lavarack, Pinebush, N. Y., and D. W. Richards, Roanoke, Va. App filed Sept. 28, 1926.

1,667,581. Battery-Terminal Clip; E. M. Bailey, Woodsdale, N. C. App. filed March 5, 1926.

1,667,585. Automatic Arc Welding; V. J. Chapman, Schenectady, N. Y. App. filed May 22, 1926. With means for oscillating the source of heat across the work.

1,667,586, 1,667,587. Apparatus for Fusion Welding; V. J. Chapman, Schenectady, N. Y. Apps. filed Aug. 2 and 30, 1926.

1,667,595. Temperature-Control Means; S. Halle, Colorado Springs, Colo. App. filed April 5, 1921.

1,667,612. Flow Meter and the Like; L. W. Thompson, Schenectady, N. Y. App. filed Sept. 22, 1922.

1,667,617. Terminal Block for Current Transformers; E. J. Zelt, Fort Wayne, Ind. App. filed Aug. 29, 1927.

1,667,624. Electrical Measuring Instrument; A. J. Corson and S. C. Hoare, Lynn, Mass. App. filed Oct. 17, 1924. With a temperature compensating arrangement.

1,667,633. Power System; C. MacMillan, Schenectady, N. Y. App. filed July 26, 1923. As applied to driving a ship.

1,667,636. Cable Grip; A. H. Nero, New Britain, Conn. App. filed June 8, 1923. Pendent fitting.

# New Trade Literature

MOTOR MAINTENANCE EQUIPMENT.—The Martindale Electric Company, 1260 West Fourth Street, Cleveland, has issued catalog No. 10, covering its motor maintenance equipment. This catalog contains twelve new products since the issue of previous catalogs and also mentions five improved products.

RECORDING LIQUID LEVEL GAGES.—Catalog No. 1800, issued by the Bristol Company, Waterbury, Conn., covers the Bristol recording liquid level gages. The various types are described and illustrated. Reproductions of the different types of charts employed are included. It contains a few methods of installing and attention is called to the electric motor-operated clock furnished with Bristol's recorders.

AIR COMPRESSORS AND TRANSFORMERS.—The General Electric Company, Schenectady, N. Y., is distributing bulletin GEA-233B, describing its single-stage centrifugal air compressors. It contains an illustration giving the construction details as well as a curve showing the operating characteristics. The company also has issued bulletin GEA-912, covering its type YU-1140 transformers for oil burners for both ignition and control.

ELECTRIC APPLIANCES. — Landers, Frary & Clark, New Britain, Conn., are distributing a new catalog covering "Universal" electrical household appliances, table appliances, table stoves, heating devices, curling irons, heating pads, etc.

AUTOMATIC CONTROL.—"Speeding Up Production with Automatic Control" is the title of bulletin No. 110 issued by the Monitor Controller Company, Baltimore, Md., in which it covers the importance of automatic control. It also contains illustrations showing the application of automatic control to machine tools, also some specific applications of Monitor control and Monitor master stations.

SWITCHBOARD DEVICES AND RECORDING INSTRUMENTS.—The General Electric Company, Schenectady, N. Y., has issued bulletin GEA-940 and GEA-584A, covering its switchboard devices, such as panel and benchboard pipe fittings, and its totalizing recording instruments and remote indicators.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered, further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number:

An agency is desired in Berlin, Germany (No. 30,961), for cloth cutters and sewing machine motors.

An agency is desired in Medan, Sumatra (No. 31,010), for flash-light cases and batteries.

Purchase is desired in Dresden, Germany (No. 30,956), of electric heating appliances and ventilators.

An agency is desired in Santo Domingo, Dominican Republic (No. 30,947), for household electrical appliances and wiring supplies.

An agency is desired in Montevideo, Uruguay (No. 30,970), for household electrical appliances, wiring supplies, shades, globes, ranges, etc.

Purchase is desired in Copenhagen, Denmark (No. 31,005), of insulating material, ebonite parts, and signal boxes.

An agency is desired in Stockholm, Sweden (No. 31,009), for electric machinery and instruments and X-ray equipment.

Purchase and agency are desired in Sydney, Australia (No. 31,006), for fractional horsepower motors.

Copies of specifications for a 50 kilovolt switchgear and steelwork required for the Arapuni Scheme in New Zealand have been received from trade commissioner Julian B. Foster, Wellington. A copy of this specification is available in the Chicago district office and also in Washington. The closing date for tenders is July 10, 1928.

## *Business Called Into Action*

ITS sixteenth annual meeting in Washington last week showed the Chamber of Commerce of the United States to be stronger and more representative of American business than ever. In a country that tops the world, so to speak, it is to be expected that a democratic body like the chamber will acquire with years inspiration for greater and better endeavors and also increase in moral stamina; otherwise it could neither wield much influence nor impart any of that motivating force which emanates from leadership and which American business must have to encourage and sustain it.

Outwardly all these qualities were visible at Washington only because the inner organization, containing the hewers of wood and drawers of water, was functioning. It is in the thoroughness of its detail work that the Chamber of Commerce of the United States makes its appeal, and its machinery of organization is geared to serve American business effectively and economically. This year the chamber seems to have struck a high note, and although the sound may not have been heard or heeded in the halls of Congress, the business world and the local chambers of commerce will carry out the program and make it effective.

## *Keep the Escutcheon Clean!*

AS THE time approaches for Congress to adjourn—and for obvious reasons many Senators and Congressmen are anxious to get away early—the legislative outlook is promising. That is to say, little affecting the electrical industry will be enacted into law. On the Boulder Canyon bill are beginning to appear the dew and clammy coldness of death. The Muscle Shoals measures may succeed in getting before a hostile conference committee, but any conference report now appears hardly likely of passage. No other major legislation affecting the industry is pending.

Of course, it is to be expected that the Federal Trade Commission will continue its hearings and report monthly. It has already uncovered unsavory material which is being interpreted and played up in a way not complimentary to the electric public utilities. Viewed with even friendly eyes, the exhibition is not attractive, and wisdom and prudence dictate some heroic action on the part of the industry to thwart growing congressional unfriendliness and possible undermining of general public relations. The picture, however, is not so bad as it is painted.

Financially, the investors show greater faith in the industry than ever, and reports of operating companies more than justify that faith. Neither the Federal Trade Commission nor the Senate can nullify the economic laws upon which the continued growth of the electrical industry is predicated. None the less, the industry must not on that account permit the public to gain the impression that electric public utilities have been recreant to the trust reposed in them. The industry is obligated to render the very best service at the lowest possible rates. That motto is emblazoned on its shield, and when mud, no matter how much, is thrown at it, the mud should be quickly washed off and the shield reburnished, so that the message may never be lost to public view.

* * * *

## *Radio and Regulation*

RADIO sets using alternating current should be equipped with a voltage-regulating device. Light and power companies are expected to regulate voltage at generating stations and substations to a degree which will give satisfactory service to all devices attached to outlets in the homes, but they cannot be expected to provide voltage regulation which will always give the best possible service to radio sets. The wiring in the homes, the use of many household devices and other factors inherent in a large utility system introduce cost and jurisdiction items beyond the control of utility executives.

Radio reception is a precision service, and, for a minimum of cost, the best place to adjust for precision service is in the radio set. Tap-changing transformers, a rheostat or other means can be used to tune a set for the home voltage when the radio equipment is first installed. Once adjusted for voltage conditions in each home, the set will give satisfactory service. Radio manufacturers and utility executives should agree on a joint policy while alternating-current radio is in its infancy. Both will suffer unless the voltage problem is solved as a co-operative task.

* * * *

## *System Insulation Improved*

BETTER standards of service demand standards in system insulation that are rational and in advance of past practices. Hit-or-miss changes in insulation in the several parts of a system should give way to a co-ordinated plan that evaluates all system factors at each insulation point. This logical policy was stated by Philip Sporn at the New Haven meeting of the American Institute of Electrical Engineers last week; but the carrying out of the principle is difficult.

Insulation is a composite substance whose strength varies greatly with the materials used and with the physical test that can be had to give quantitative data on insulation strength, and as yet insufficient knowledge of lighting exists to permit the specification of tests which will duplicate the possible service experiences of insulation. And, finally, either grading a system or making a system have uniform insulation introduces economic values and different service conditions which are not conducive to standardization. System engineers, however, can use part of the principle to advantage. If, as at present, money is spent to raise line insulation, then money should be spent to raise terminal equipment insulation so as to maintain relative values at least, and it may pay to raise the insulation of the terminal equipment to a higher level than that of the line.

The goal in insulation is continuous service for all the system. Any grading which makes weak spots in insulation may protect physical apparatus at the expense of system service; but such a policy is unsound except as a temporary expedient, and in this event the relief valve should be simple, inexpensive and least hazardous to continuous service. Until the actual phenomena that may occur on a system are known quantitatively there is little need for hard-and-fast rules for system insulation. Awaiting such knowledge, insulation must be the outcome of a mixture of experience, money, guesswork and good judgment.

* * * *

## *Indirection Pays Poorly*

ONE lesson of the Federal Trade Commission's investigation of the electric power industry is this: Indirection does not pay. The utilities organized a wide-flung and apparently efficient bureau of information for the purpose of supplying the press and public with facts regarding electric, gas, telephone and electric railway service. Basic facts were printed in booklet form for use in schools, and other material was distributed to the press. The articles were cleanly labeled by the organizations that issued them; there was no anonymity, no attempt to evade responsibility, nothing to justify the adjective "insidious." Those to whom the reading matter was sent knew its source, and they were free to accept or reject it as their informed judgment should dictate. Many of them accepted it.

Now comes the wind from Washington to uncover what every one already knew. The information is condemned in the public prints as propaganda. The authors are pilloried as "the power trust"—which, of course, they are not. The industry gets blasted with column upon column of hypocritical criticism from many of the very papers which had published its material. It gets singed and crisped with the hot alibis of the very authorities who accepted its booklets as school texts. From which we cull the lesson that indirection hardly pays.

Now, there are many methods a business organization can employ in presenting its case to the public, and one of them is advertising. The forthrightness of paid advertising appeals to our American sense of square dealing. We figure that normally the advertiser must have faith in his business or he would not pay out good money to talk about it. The electric light and power industry should adopt this method of talking to its public more than heretofore, not alone because the method is more acceptable and effective than others, but because the industry cannot afford to neglect this avenue of publicity. The public information bureau proved somewhat of a boomerang. Much of the good it accomplished was wiped out by the denunciations which burst forth as a result of Washington inquiries. What the industry should now use is straight advertising—and plenty of it.

The National Electric Light Association should advertise liberally in telling the country about the merits of electric service. Every individual company should consider it a matter of course to use space in local papers. And the advertisements should be aggressive and not defensive. The industry should seek business, not sympathy, and it should do it soon.

* * * *

## *Railroad Power Contracts and Use of Utility Service*

PROSPECTS are brightening for the increased use of purchased power by electrified steam railroads. Central-station men must rejoice at such expressions of hospitality toward their product as were heard last week at the New Haven regional meeting of the American Institute of Electrical Engineers from men like Vandersluis, Withington and Hill. It is highly gratifying to learn that the use of purchased power tends to increase service reliability in a field where interruptions are simply intolerable and that such insurance is worth a premium over the cost of producing energy in an isolated station owned and operated by the railroad interests themselves. Apparently the most advanced opinion in railroad circles recognizes the importance of being free to perform the specialized task of moving commodities and living freight from place to place with maximum economy.

Railroad power business, however, does not come to the modern utility on a silver platter. The discussion at New Haven brought out very clearly the importance of negotiating contracts on a liberal basis as regards the customer's operating situation. The problem of demand charges is at the forefront of current railroad thinking, and it is significant that most painstaking specification of this element is embodied in the recent Illinois Central and Pennsylvania Railroad contracts with the power companies serving them. In the former case the transportation company is allowed to exclude from billing abnormal peaks due to stated recognized emergencies. In the latter a clear-cut expression of how demands are to be determined provides for service capable of being expanded over a long period of years. The speakers made the point that the advantages of interconnection should be availed of in fixing demand charges and intimated that the modern railroad's inside position in the fuel and capital markets should also be recognized in the negotiation of power sales, cost of production being thereby made the base of energy rates.

Power companies are under no obligation to sell energy to railroads at a loss, and we do not believe this class of customers desires them to do so, if, indeed, the regulating commissions concerned would permit such discrimination. Obviously a power contract, whether made with a railroad or with a manufacturer of neckties for the Zulus, must be profitable to each party in the long run if it is to endure in good relations. The railroads seek to obtain the best service at the lowest prices available, just like any discriminating buyer. Per contra, well-run power companies desire a fair profit on the business which they handle after all costs are met. All that the situation requires is a thorough study of the possibilities and equities of each particular situation, which then should find expression in a contract just to both sides and one designed to encourage the use of the service to the utmost desirable extent. The fine indorsement of purchased power at the New Haven meeting of the Institute should not be allowed to blind central-station men to the railroads' suggestion that various aspects of the economic problem deserve more thorough analysis in dealing with specific cases. The test of a good contract is its successful application, and no better evidence of this can be had than the satisfaction of both parties with an instrument which encourages the growth of business transacted with each other as the total volume of service rises.

* * * *

## *Fixed-Par Versus No-Par Stock*

THERE is an unwarranted misunderstanding in many minds regarding the relative merits of par and no-par stock. It is less a question of merit than of significance. The price paid for a share of stock by the original shareholder is not important. Invested capital appreciates as earnings are turned back into the company or as the market or replacement value of corporate properties increases. Invested dollars depreciate with profitless operation and adverse economic conditions affecting real estate or replacement costs. The equity of the stockholder is always his per-share interest in a hypothetically liquidated concern. This amount may, and in fact must, at any conceivable instant after organization be either more or less than the sum paid in by him in assuming partial proprietorship.

The establishment of a par value represents an effort of historical interest to stabilize artificially a thing which very evidently cannot be stabilized in this way, however satisfying arbitrary assumptions may be. Par value is a term possessing no significance whatever, and, rather than affecting the rights of either stockholders or the public, it has no possible influence upon them—other than to render confused that which is amazingly simple. A fairly-arrived-at book value, per share, at the instant under consideration is the only proper par. Nothing may be added to or taken away from the equity of the stockholder or the value of the property by arbitrary statements or assumptions of value.

* * * *

## *Economic Balance in the Electrical Industry*

A THOUGHT for electrical men as well as those connected with other industries came out of the convention of the United States Chamber of Commerce in Washington last week. There was naturally much said about the "new competition," the overproduction of commodities and the need for an intelligent attack upon the organizing of distribution in this country—the need for setting about the task and not just talking about it. More than one eminent speaker contributed to the crystallizing of this sensible conception. American industry is not suffering, they said, from too much production, but from production that is not in balance with consumption. We are not producing more things than people can use, but too often the wrong things, and the problem of the future will be to organize, regulate and correlate the supply and the demand. In a word, we must stop manufacturing more buttons than there are buttonholes, so to speak, and laying off for lack of market textile hands who are ready to work, when their own children need shirts that they are able to produce. Clearly this is neither logical, humane nor economic.

What does this mean in the electrical industry? For one thing, we have not in the past thought ahead and prepared the way for expanding markets in the home, store and factory by seeing that installations were made adequate for future needs when the wiring was put in. And so we see today power companies needing load and jobbers and manufacturers needing market that is blocked for lack of outlets. Meanwhile there are too many contractors suffering for lack of jobs, yet able and eager to install this wanted wiring—all owing to a lack of balanced preparation for future growth. Lack of industry statistics has prevented men forecasting the trends of growth and sensing the changing conditions, and factories have forged ahead, increasing capacity and intensifying competition, when often what were needed were goods quite different.

The future will demand more intelligent thought and unselfish planning, more market knowledge, more preparation and preadjustment for balanced development and growth. In the past there has been co-operation only when it was necessary to meet present and immediate embarrassment and need, but in the years ahead electrical men will have to learn to co-operate and organize to provide in advance for coming conditions and prevent the economic evils that inevitably follow the unbalancing of production, distribution and consumption in any market.

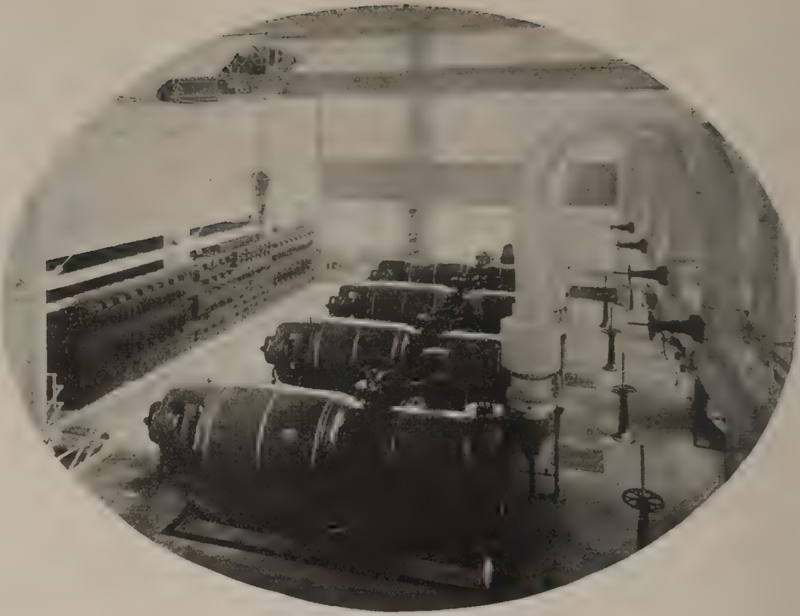
* * * *

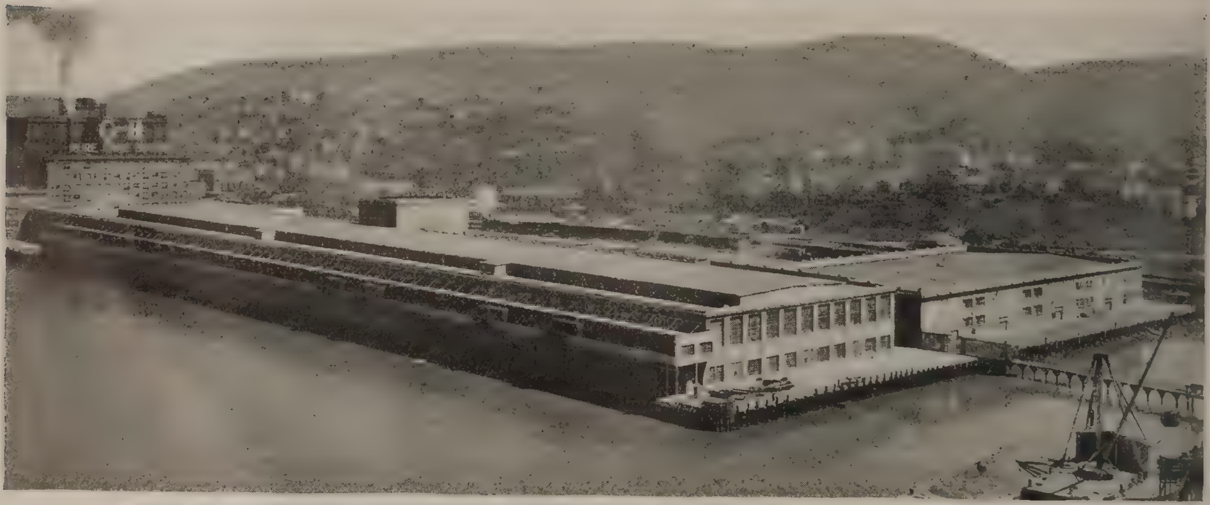
## *Code Work and Industry Progress*

CODE work and the progress of the industry are so intertwined that there can be no separation if the code is to serve the best interests of the electrical art. At the meeting of the electrical committee of the National Fire Protection Association held this month, and later at the N.F.P.A. meeting, the 1928 code was accepted, subject to a letter ballot of the electrical committee, after which it will be sent to the executive committee of the N.F.P.A. and later to the American Engineering Standards Committee. While the correlating committee, which was appointed by the electrical committee at its last meeting to whip the code and the mass of new rules into shape, was not in a position to do as complete a job as might have been done prior to the February meeting, yet many rules were covered in the 1928 code that should prove valuable to the industry.

There are three major problems on which the attention of the article committees and the electrical committee must be focused in the future. They are: (1) To get into the code such rules as should have been incorporated prior to the 1928 code; (2) to add rules to cover the industry's current needs; (3) to bring the code up to date and to keep it in step with the progress in the art. The responsibility for the solution of these problems lies not with any one branch of the industry. It is a joint co-operative task. The code is a national institution, and a great deal of effort has been expended in the last three years to make it so. Any further growth of local regulations will tend to denationalize the code. Such regulations, regrettable as they may be, are invited if the code fails not only to catch up with the progress in the art but to keep constantly in step with it.

# *Production Processes in This Mill Co-ordinated by Electricity*





ELECTRICAL applications in the plant of the California & Hawaiian Sugar Refinery at Crockett, Calif., have been an important factor in synchronizing production units and have made possible an uninterrupted flow of product from the receipt of raw sugar to delivery at the shipping platform. Automatic and semi-automatic control at key stations has reduced labor costs and removed the human element in co-ordinating production units. Hundreds of thousands of bags must be transported by conveyors. The applications are discussed in the following pages.

# Electricity in Sugar Refining

### Engineers of California & Hawaiian Sugar Refining Corporation produce electrical designs which speed up production and synchronize plant operations

By Louis F. Leurey
*Consulting Engineer, San Francisco, Cal.*

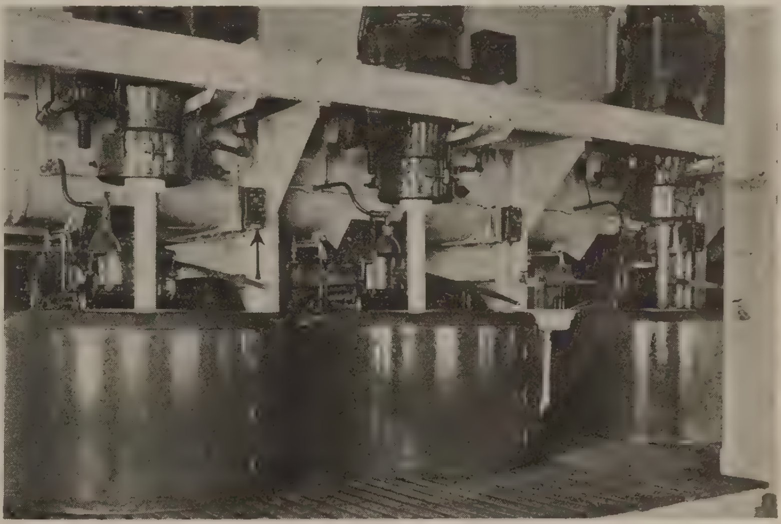
IN THE development of electrical usage at the plant of the California & Hawaiian Sugar Refining Corporation the engineering department has not been satisfied in applying all of the well-known methods of electrical drive and control but, being notably "electrically minded," it has gone extensively into the application of electricity as a medium in the accomplishment of industrial processes.

These engineers, in common with all engineers experienced in the manufacturing field, know that the greatest obstacle to synchronizing the various factors of production is the human element. Attacking the problem from this angle, they have made a special study of the salient factors which impede the uninterrupted flow of their product from the receipt of raw sugar to delivery at the shipping platform. They have found that the use of automatic and semi-automatic electrical control at certain key stations has not only reduced labor costs but has been a vital factor in co-ordinating the control of production units. Some of these applications are of consequence only in the sugar-refining process, but a number of important installations will be described where a similar application could be made to other products and are therefore of general interest in the manufacturing field. Before taking up the electrical applications in the plant it will be well to describe briefly the methods used in the process of refining sugar.

The plant of the California & Hawaiian Sugar Refining Corporation is situated at Crockett, Calif., on the shores of San Francisco Bay, and has a deep water frontage of 3,000 ft. It is served by ocean steamers, river craft and by connections to three transcontinental rail systems. The raw sugar is received in cargoes up to 14,000 tons from the Hawaiian Islands, and the Matson Navigation Company maintains a fleet of modern sugar-carrying vessels which transport up to 90,000 tons of raw sugar per month. The plant has a melting capacity of 2,500 tons of sugar per day, which is converted from the raw state into the various forms of refined product demanded by the American market.

Raw sugar comes from the Hawaiian Islands in 125-lb. bags, of approximately 98 deg. purity, which is landed from the ship's side in slings and conveyed directly to the refinery or to warehouse storage. The general refining process consists of the following operations:

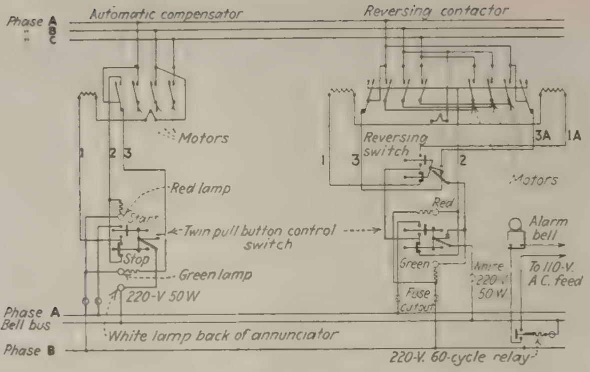
(a) *Washing* (Removal of External Impurities)—At the end of the main conveyor belts is a raw sugar bin, of 1,500 tons capacity, from the bottom of which the sugar is lifted in bucket elevators to a "mingler," where it is thoroughly mixed with syrup to give it "flow." The resultant mixture, called "magma," is allowed to flow into motor-driven centrifugals, where it is automatically washed by spray nozzles, thus raising its purity from approximately 98 to approximately 99.4 deg. Twenty-two raw sugar centrifugal machines, each one of which is driven by a 30-hp. motor, are required for this operation.



*Raw sugar centrifugal station, consisting of 22-30-hp. motors driving centrifugal baskets*

(b) *Melting* (Changing the Solid Raw Sugar into Liquid Form)—From the centrifugals the washed sugar drops into a cylindrical tank, where it is partially dissolved with hot water and stirred by revolving paddles until it reaches a concentration of 66 per cent of solid matter.

(c) *Filtration* (Removal of Insoluble and Soluble Impurities)—From the melting tank the solution is pumped to the top floor of the "char house," a nine-story building, where it is delivered to tanks and heated by steam coils to a temperature of 176 deg. F. At this point lime and kieselguhr (diatomaceous earth) are added. The kieselguhr absorbs some of the impurities



*Wiring for remote control of warehouse conveyor motors*

and in addition forms a porous coating against the filter cloths through which the sugar liquor passes. These filter cloths are contained in modern filter presses which remove from the liquor the insoluble impurities. From the filter presses the liquor is delivered to 108 char-filters. These char-filters each consist of heavy cast-iron tanks 10 ft. in diameter and 25 ft. in height, each containing 50 tons of "bone char," which is an animal charcoal ground to size between a 10- and a 30-mesh screen and calcined at a temperature of 1,200 deg. F. This filtration removes practically all of the coloring matter and considerable portions of the organic and mineral impurities present.

(d) *Crystallization* (Conversion of the Liquor into Sugar Crystals)—The sugar liquor now being pure white, with the greater part of the impurities removed, is then boiled under vacuum at low temperature in vacuum pans approximately 14 ft. in diameter and 17 ft. high. In approximately 1½ hours 38 tons of granulated sugar is delivered from these pans.

(e) *Drying*—Crystals from the vacuum pans are then spun in white sugar centrifugals, equipped with an automatic electrically controlled water spray, which washes and partially dries the sugar crystals. Final and complete drying is effected in an apparatus consisting of two large cylindrical drums, 6 ft. in diameter and 30 ft. long, each revolving with a slight downward pitch from the receiving to the discharging end. The first, or upper, "granulator" revolves slowly and carries on its inner edges narrow sawtooth shelves which cause the sugar to fall in a shower throughout the entire length of the drum. A strong current of air heated by steam coils and driven by a powerful fan is drawn through this "granulator" and dries the sugar to 0.1 of 1 per cent of moisture. The final drying is done in the lower drum or granulator carrying an internal steam heated drum about 24 in. in diameter, which revolves with the granulator. The sugar crystals fall in a shower from the shelves onto

*Control of automatic bag-filling and weighing machine* this hot inner drum and are dried to a moisture content of about 0.05 of 1 per cent.

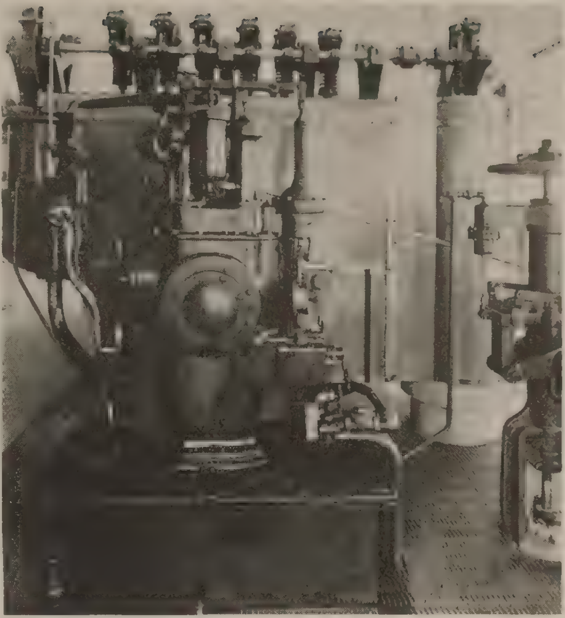
(f) *Sorting and Packing*—From the granulator the sugar is passed over separators which screen the crystals and sort the grains into coarse, medium and fine sizes. The sugar is then conveyed to the packing room. As many as fourteen grades of refined sugar are produced and packed in more than twenty various types of containers. The final product is of extreme purity, each grade being absolutely uniform as to color and granular structure, and in the entire process from raw sugar bin to final packed product it is at no time touched by the hands of the operators.

In addition to the main process described above, there are many intricate problems connected with the extraction of sugar from sweet waters and low-grade syrups, all requiring labor, machinery and fuel. It is sufficient to say here that these recovery operations are carried out to the limit of commercial economy.

### CENTRAL POWER PLANT

As great quantities of steam at low pressure are required in the process of sugar refining and as all of this steam must necessarily be generated at standard boiler pressures a steam turbo-generator plant was designed to act as a pressure reducer between the boiler room and the low pressure mains. In this way all electrical power required for the refinery is recovered as a byproduct of this pressure-reducing process. The cost of electrical energy consists of the sum of the fixed charges on the turbo-generators and the turbine building, plus the annual operating costs of the turbines and the thermal loss between the throttle and the discharge pipe. The sum of all of these charges is much lower than the cost of purchased energy even under the favorable load factor of sugar refinery operation.

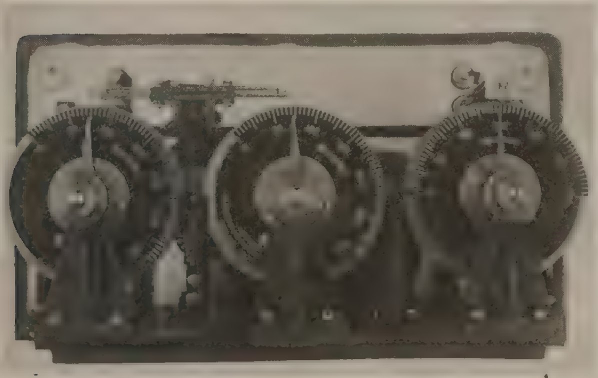
When it is considered that this power plant operates eleven months in the year, generating approximately 100,000 kw.-hr. per day, with an average load of 4,000 kw. and a maximum load of 4,500 kw., it can be readily appreciated that the power plant makes a very substantial return upon its investment. Three 1,500-kw., 440-volt, three-phase turbo-generator units exhaust directly into the 10-lb. low-pressure steam mains and do the regulating necessary for the electrical system. A fourth 1,500-kw. unit of single-stage design exhausts directly into the 70-lb. mains that supply the refinery vacuum pans.



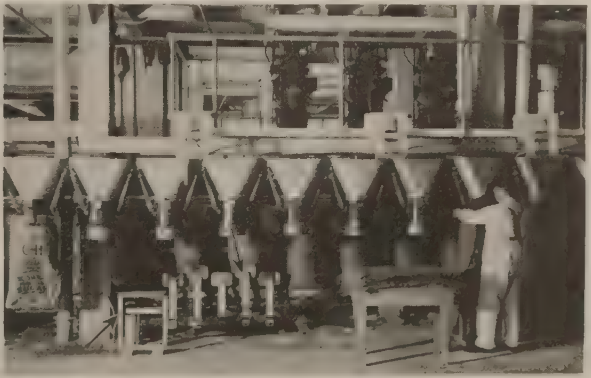
*Close-up view of speed governor, pressure governor and valve gear, high back-pressure turbine*

This high back-pressure turbine is of considerable interest due to several unique features incident to its operation. Requirements of the vacuum pan are such that a steady pressure is demanded, so that it was necessary to develop a pressure governor which would maintain a constant pressure over an adjustable range of from 55- to 70-lb. gage. The second requirement was that in maintaining this pressure the safe electrical output of the generator must not be exceeded, and the third requirement was that this machine must operate in parallel with the machines on the 10-lb. system.

The turbine, which is of General Electric manufacture, has met all of these requirements through a very ingenious design by the manufacturer. A mechanical pressure governor, as illustrated, has been incorporated with the hydraulic speed governor in such fashion as to maintain very steady pressure over a wide range of steam demands, and a contact-making ammeter acting on the pilot control motor of the speed governor oper-



*Close-up view of motor-driven supervising relay for controlling raw sugar station*



*Automatic electrically controlled bag-filling and weighing machine* ates successfully as a load-limiting device whenever the turbine's electrical output exceeds a predetermined limit.

The vacuum pans often require more steam than can be handled by the high back-pressure turbine, and a Shield regulating valve, designed by the master mechanic of the sugar company, supplies the make-up steam directly from the boiler room mains. Two of the accompanying charts, taken from flow meters, indicate the steam passing through the turbine and the make-up steam supplied by the Shield regulating valve during a typical operating day.

### Switchboards and Feeders

The main switchboard is of very simple design and controls four 3,000-amp. generator breakers and 21 500-amp., 440-volt feeder breakers. The feeders from this switchboard are all of uniform capacity, consisting of 500,000-circ.-mil varnished cambric cables in 3-in. conduit. They are designed to handle sections of the refinery and each feeder is equipped with a watt-hour meter to determine departmental power costs and to check load growth in various departments of the refinery. Distribution switchboards, as illustrated, are of steel construction, totally inclosed front and rear and solidly grounded. All switches are equipped with a corporation lock, and painters are permitted to paint switchboards unattended in the same manner that they would paint tanks or building columns.

All sub-feeders in the refinery, with the exception of those controlling motors of more than 50 hp., have a uniform capacity of 100 amp. each and are so routed in the refinery areas as to accumulate a load equal to their wire capacity. Feeders of this "busbar" type connect to two or more motors until they are fully loaded to wire capacity, and the size of the feeder remains unchanged from the switchboard to the last motor. By the use of this system of sub-feeders and of fully loaded main feeders all copper in the entire refinery is operating near its full efficiency, the only exception being the copper in the individual motor circuit, where size is governed by the requirements of the National Electrical Code.

There are approximately 200 fractional horsepower motors in the refinery and 800 motors of the three-phase, 440-volt type in sizes from 1 to 350 hp., totaling approximately 12,000 connected horsepower. The average size motor in the refinery is only 15 hp., but in spite of this small average size it has been possible to maintain a station power factor of from 83 to 84 per cent This has been accomplished by the judicious loading of induction motors and the use of synchronous motors of 150 to 350 hp. in driving pumps and air compressors, and by the further use of a static condenser at the terminal of a main feeder of especially low power factor.

Motor controls are grouped wherever possible at conveniently accessible locations and the various starters and disconnecting switches are all of the "ironclad," fully protected type, mounted on steel panels fabricated at the refinery to standard dimensions. This grouping of controls has resulted in more frequent inspections, lower maintenance costs and fewer interruptions to machine operation. All motor starters now purchased are of the automatic type, but old manual starters are being retained as long as they prove useful.

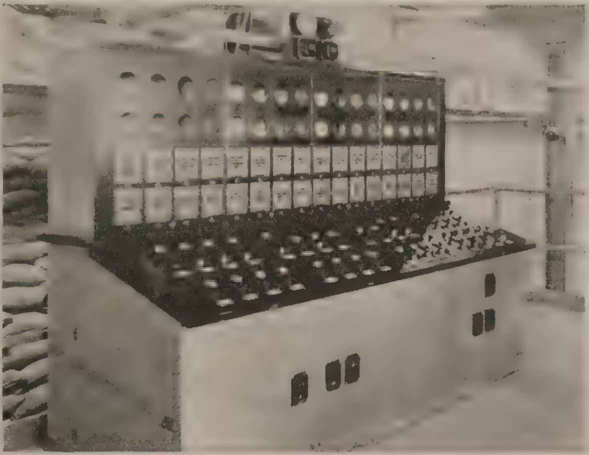
### Special Applications and Controls

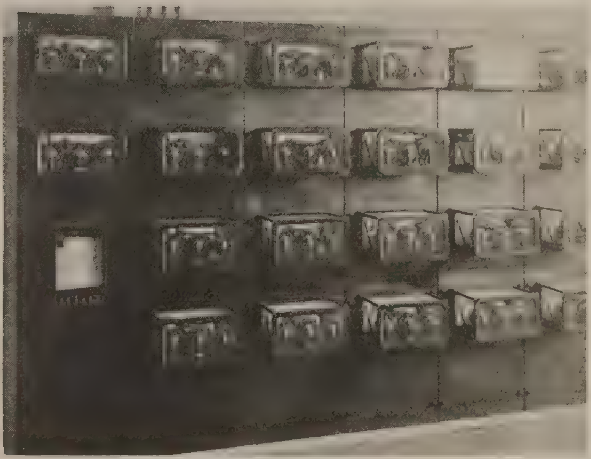
The raw sugar washing station, as shown by one of the accompanying illustrations, consists of a group of 22 centrifugal sugar washers, each driven by a Westinghouse 30-hp. high-torque motor. The motors are directly connected to centrifugal baskets by centrifugal clutches that engage after the motor has partly come up to speed, the motor itself being thrown directly across the line by means of a magnetic contactor. Each centrifugal is automatically controlled by a three-dial, motor-driven supervising relay (illustrated) which is energized by the same push-button that is used to control the starting contactor of the 30-hp. motor. Each timing dial of this supervising relay can be independently adjusted and automatically set to:

First—Control the time of admission and duration of the water spray applied to each centrifugal.

Second—Control syrup stream by which first washings of low purity are separated from final washings.

Third—Open the magnetic contactor to the 30-hp. motor and apply the brakes to the centrifugal basket.





*At right—Benchboard with visual annunciator for remote control of warehouse motors*

*Below, left—Fabricated steel switchboards controlling distribution circuits*

*Below, right—Switchboard with automatic supervising relays for controlling raw sugar washers*

In addition to these automatic operations there are five push buttons, as indicated on the accompanying control diagram of the automatic sugar washer. Each of these push buttons gives independent manual control without in any way interfering with the operation of the supervising relay, as follows:

Push Button No. 1—Releases the brake, closes the magnetic switch controlling the centrifugal motor and energizes the supervising relay.

Push Button No. 4—Operates the water spray independent of the supervising relay in order to wet the centrifugal basket preparatory to filling with "magma."

Push Button No. 3—Opens the magnetic contactor to the main motor without disturbing the time cycle of the supervising relay. This feature is necessary in order that the centrifugal basket may be slowed down when loaded too rapidly.

Push Button No. 1—Must be pushed again to reconnect the main motor.

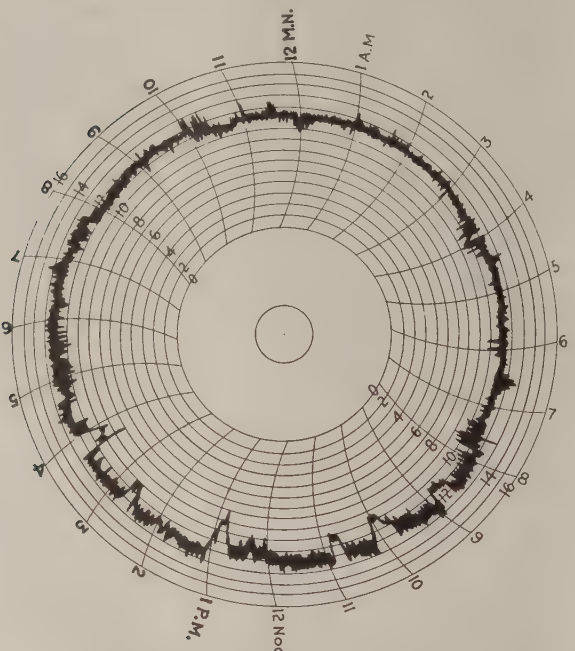
Push Button No. 2—Disconnects the main motor and applies the brake independent of the supervising relay.

Key Switch No. 5—Is for the purpose of by-passing the supervising relay and permits the operation of the centrifugals by hand control. This is necessary in making mechanical adjustment and for washing down the equipment.

The equipment described above was all designed by the engineering department of the California & Hawaiian Sugar Refining Corporation and gives an extremely flexible control of the raw sugar station. Labor charges have been reduced, a more uniform product secured and, through a better timing of operations, higher load factor has resulted at this important refinery station. It is obvious that such a control system could be applied to the washing of salt or any other product that is centrifugally separated.

One of two automatic bag-filling and weighing machines designed and built by the engineering department of the sugar company during the past season is shown in one of the accompanying illustrations. The application consists essentially of two conveyors. One, commonly called the "merry-go-round," has been in use for several years and consists merely of a succession of small platforms upon which filled bags of sugar are conveyed from the automatic weighing scales, past the sewing machine heads, to the warehouse conveyor chute. The other conveyor is suspended directly over a part of the "merry-go-round" and operates in synchronism. This second conveyor comprises a series of special hoppers, to which empty bags are attached, and which carry the bags under the automatic weighing scales. Here the weight of sugar depresses a given bag until it rests upon one step of the "merry-go-round"; the bag is released automatically from its hopper and is carried on, as indicated above.

The automatic electric control of this station, as shown in an accompanying diagram, consists of two separate circuits. Circuit "A," or the bag-holding circuit, consists of two copper bus bars mounted concentrically on the hopper conveyor framework, Within each hopper is mounted an electromagnet which operates holding arms, as shown in one of the illustrations, and clasps the bag to the hopper. These magnets are connected to the busbars by sliding copper brushes. The busbar is divided into sections, so that when an empty bag is slipped over the hopper spout by the operator the magnet is energized at 110 volts by means of a momentary contact switch closed by the knee of the operator. As soon as the bag has moved past this "loading section" of the busbar it is held in place by reduced voltage to minimize heating of the magnets, which are necessarily small so as not to interfere with the flow of sugar from the scale to the sack within the predetermined time.



*Steam input to high back-pressure turbine*

The second circuit, "B," consists of an electromagnet control on the dumping valve of the automatic weighing scales. This circuit is equipped with a timing commutator mechanically driven by the "merry-go-round" and so arranged that the automatic scales discharge at the exact moment the proper bag is beneath them.

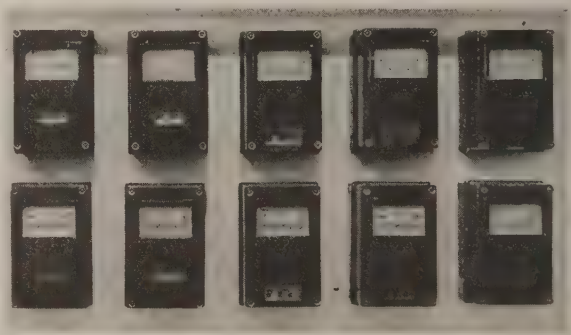
From this point the bag rests on one step of the "merry-go-round," where it first passes a tapping device to settle the sugar, and then contacts with a mechanical arm which de-energizes the bag-holding magnet and permits the bag to continue past the sewing machine heads. The installation has now been in operation for a period of six months and has not only operated with high economy but has been of still greater value in synchronizing refinery operations to a finer degree of accuracy.

As this refinery handles over its main conveying system approximately 40,000 bags of raw sugar per day from the warehouse to the refinery, and about the same number of bags of refined sugar from refinery to warehouse, it became highly important that a dependable counter be developed which would accurately tabulate this product so that the warehouse operation and the refining processes could be successfully synchronized. To accomplish this purpose it was essential that the measuring must be done at a number of points throughout the refinery and warehouse,, some of them over 1,000 ft. distant from the control station, corresponding to the load dispatcher's desk in an electric utility. Failing to find a satisfactory counting device on the market, the refinery engineers painstakingly experimented with various methods and finally developed a device which is an adaptation of the principle of an electrical demand indicator and records bags of sugar instead of kilowatts of demand. It has a recording capacity up to 10,000,000 bags of sugar before reverting to zero. A battery of fourteen of these counters is shown in one of the accompanying illustrations.

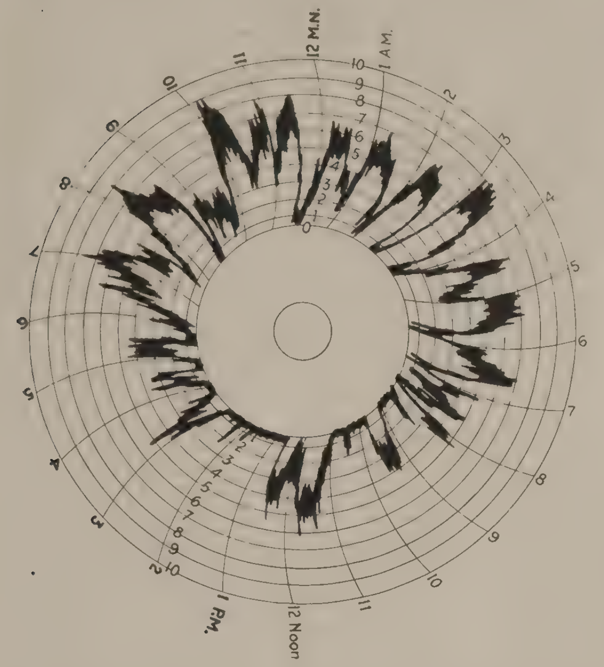
Specially designed mechanical contacting switches were developed by the refinery engineers and located at various points in the conveying system where the sugar goes down an incline, thus securing a very rapid operation of the contact. The contactor had to be made very rugged and with exceptionally high speed action in order to catch bags traveling in various positions and at various rates of speed. This contactor opens against the action of a small magnet which is installed to prevent chattering due to mechanical rebound at the time the trigger resets. These contactors have been in operation for about four years with an extremely creditable record of reliability.

### REMOTE-CONTROL WAREHOUSE SWITCHBOARD

The sugar comes to the refinery in ship cargoes as large as 14,000 tons, and a very intricate and complete conveying system has been installed so that ships might be unloaded with the least delay. In addition to taking care of the unloading of the ships, 2,500 tons of the product must be delivered to, and almost as much again received from, the refinery each working day. Some 30-odd motors are employed in driving these various conveyors, a number of which are reversing and many of which are interconnected for various transfers of product to and from storage. As the warehouses are more than 1,000 ft. long and 250 ft. wide, divided by fire wall sections, it became highly important that all conveyor operations be synchronized from a single point. This point was selected at the end of the main conveyors which lead from the warehouse to the refinery. The first design developed was a fully automatic type, using plugs and receptacles so that any train of conveyors could be



*Remotely controlled bag counters located at central control point* electrically interlocked. This design was rejected for two reasons: (1) Due to the excessive number of combinations needed to satisfy all of the requirements in transferring product. (2) Due to the fact that it would introduce too much special equipment and thus complicate the maintenance problem. It was deemed wiser to design a remote-control board, giving individual control of motor circuits without interlocking, and to use types of control equipment familiar to the operating department.



*Input of make-up steam to refinery vacuum pans as delivered from boiler room to "Shield" regulating valve*

A benchboard was designed, as illustrated, to give rapid remote control over all of these motors in order that jams on the conveyor systems could be prevented and that transfers of product could be quickly and accurately carried out. The benchboard, which is of General Electric manufacture, is designed along central-station lines, except that 440-volt control equipment is used instead of the conventional 110-volt. Multi-conductor No. 14 B. & S. gage wire is used between the benchboard and the automatic motor starters and contactors in various sections of the warehouse. Three wires are used to control an ordinary operation and five wires are used to control a reversing operation.

Conventional red and green bull's-eye lamps with red and green mechanical indicators are used on each control switch, the lamps having a 440-volt resistor between them and the source of energy. In addition to these lamps on the benchboard, there is a ground glass visual annunciator mounted on the vertical section of the switchboard. If a motor stops, due to overload, no voltage or from any accidental cause, a white light flashes behind the ground glass annunciator and illuminates the painted name or number of the conveyor, and at the same time an auxiliary gong in parallel with the white light is sounded. The operator then manually disconnects all motors that are driving conveyors in train with the conveyor in trouble. A pull on the green or stop button of the troubled conveyor clears the white light and bell by means of an auxiliary finger.

Operated in conjunction with this system of control is a 12-volt direct-current signal system with return call push buttons and bell. The bell on this system is connected in parallel with a red lamp mounted back of the ground glass visual annunciator which flashes the name of the conveyor whenever a signal comes in. Reset buttons are mounted on the switchboard for clearing this light after the operator has heard the signal and identified the conveyor.

All motors are normally started and stopped on bell signal from the motor station, and emergency stops are made at the benchboard whenever a motor kicks out in a conveyor train. Safety buttons are also installed at convenient points near the motors and conveyors so that emergency stops can be made when necessary.

This switchboard has proved highly satisfactory in expediting warehouse operations and in cutting down the losses incidental to jams that previously occurred when a single conveyor, operated in train, fell out of step. It is planned, as will be seen from the accompanying illustration, to install ammeters in each motor circuit so that the operator on the benchboard will have continuous knowledge of the loading and operating condition of each conveyor in the system.

In conclusion, it is only fair to point out that the achievements of the engineering department of the California & Hawaiian refinery in these advanced applications of electricity were all made in the face of many discouraging circumstances, among which may be cited the tremendous pressure required by the routine operation of such a large plant, and, secondly, due to the fact that very little, if any, standard equipment could be applied to the work in hand, especially as the refinery is situated several thousand miles from the great manufacturing centers of the electrical industry. Under these circumstances the important and successful applications made could only have been carried out by engineers of an enthusiastic type, and above all by engineers who were "electrically minded."

## Cost of Steam Plant Equipment

FROM the data sheets of a large steam-driven central station the following field installed costs, excluding general job and contractor's compensation and overhead, are taken as of 1927:

STEAM PLANT EQUIPMENT COSTS, 1927

| | |
|---|---|
| One Ingersoll-Rand two-stage, horizontal type 10, water-cooled, 12x12-in. air compressor, 60-in. flywheel, 10x⅜-in.x15-ft. long leather belt and 50-hp. motor, 2,200-volt, three-phase motor | $4,512 |
| One air compressor, Kellogg self-contained, chain-driven model 42-250, 1-hp. motor, 110 volts | 358 |
| One air compressor, Westinghouse air brake locomotive type, 6x12x10-in.; steam end, 8x12x10-in.; air end, 2-in. steam outlet, 1½-in. steam inlet | 522 |
| One 1,000-gal.-per-minute centrifugal fire pump. 1,650 r.p.m., 8-in. suction, 6-in. discharge, direct-connected to Westinghouse turbine, single-stage impulse, 200-lb. gage, 100 deg. superheat | 4,342 |
| One 3,500-kw., 100 per cent power factor turbo-generator unit, 1,800 r.p.m., 180 lb. steam pressure, 20 deg. superheat; generator 2,300 volts, three phase, 60 cycles, with oil pumps for turbine | 71,886 |
| One jet condenser, Westinghouse LeBlanc, turbine driven, handling 2,380,000 lb. of water condensing 58,450 lb. steam per hour to 28-in. vacuum with cooling water at 40 deg. to 70 deg. F.; one centrifugal pump driven by 15-hp. motor, and one 5,240 gal.-per-minute centrifugal condensate ejector pump, one vacuum air pump and one 143-hp. turbine (non-condensing), 1,000 r.p.m. | 12,333 |
| Pedestal and foundation | 2,951 |

# Ventilation Control in the Moffat Tunnel

By H. C. Glaze and M. P. Bailey

*General Electric Company*

FAN ventilation is used by the Denver & Salt Lake Railroad in removing smoke and gases from the recently completed Moffat Tunnel through the Continental Divide in Colorado. All ventilation is accomplished at the east portal through the use of two fans located in separate compartments of a specially designed structure. Control equipment is installed in this building.

*Control plan for ventilating fans and dampers*

Each fan is driven by a 2,200-volt, slip-ring, induction motor. As the barometric pressure varies considerably between the two portals during different seasons of the year, motors of different capacities are used, one of 750 and the other of 500-hp. Only one fan is operated at a time, the selection depending on the traffic and the barometric pressure. The speed of each motor may be reduced 20 to 25 per cent by means of a resistor.

A door installed in the tunnel at the east portal confines and directs the air in the tunnel. This door in opening slides upward and is actuated by a 10-hp., high-resistance, squirrel-cage motor.

Under certain conditions fresh air is forced through the tunnel from east to west, while under other conditions the smoke and gases are exhausted from the tunnel from west to east. The fan rotates in but one direction, dampers being provided to change the direction of air flow and to control the several openings. By suitably adjusting these dampers the air can be forced into or discharged from the tunnel.

As a train approaches the tunnel from the east it closes a track circuit, thus causing a track relay to energize a reversing magnetic starting switch. This switch opens the tunnel door by means of the 10-hp., squirrel-cage motor previously mentioned, and allows the train to enter the tunnel. As the last car leaves the track circuit the relays drop out, energizing the "close" contactor of the magnetic starting switch. When the door reaches the closed position a limit switch trips, completing a circuit for a contactor, which in turn closes a triple-pole, 300-amp., high-voltage, oil-immersed line contactor governing the fan motor. The latter automatically accelerates through suitable contactors to 80 per cent speed by means of definite-time control. Any increase in speed above 80 per cent is obtained by means of a master switch. When a westbound train passes out of the west portal the conductor telephones the station attendant at the east portal, who, if traffic conditions permit, can shut down the fan by means of a push-button station.

A train approaching from the west makes contact with the track circuit inside the tunnel at some distance from the door, causing the track relay to complete the circuit to the reversing magnetic switch. The various devices then function in a manner similar to that for the westbound train. The door may be opened at any time, from a push-button station.

As the railroad company intends to operate but one motor at a time, only one control equipment has been installed. This may be used for either motor and includes one three-phase, 2,200-volt, incoming line and feeder panel with the usual instruments and circuit breaker with overload and undervoltage trip; a speed regulating starter panel, containing the necessary secondary accelerating contactors, regulating contactors, accelerating and control relays, as well as the necessary push-button stations, limit switches for the tunnel door, and a master switch. On the secondary panel there is a reversing magnetic switch for controlling the 10-hp., 220-volt, squirrel-cage motor operating the door at the east portal.

Each of the dampers is controlled by a 3-hp., 220-volt motor operating a suitable mechanism. They are interlocked in such a way that the fan motors cannot operate until proper dampers are completely opened or closed, as the case may be.

# Engineering for Economy*

### Objectives for action outlined. Planned development. More research. Better personnel. Broader perspectives. Economic approach

By E. C. Stone
*Chairman Engineering National Section, N.E.L.A.*

Until a very few years ago the leaders of our industry were primarily concerned with reducing the cost of energy. Much success has been attained in this line, and the cost of energy has now become such a small part of the total cost that it is necessary to look elsewhere in the future for major economies. On the other hand, the tendency to build large power plants at points more and more remote from the load centers, involving more extensive transmission systems, and the insistent demands for greater and greater reliability of service, as well as other less important influences, are giving the unit cost of system investment an upward trend. This fact and the vast reductions that have been made in unit fuel cost are making the fixed charges on system investment an element of constantly increasing importance in the overall cost of electric energy delivered to the user. The system investment is therefore the most logical place to look for further cost reductions.

The first objective, to obtain "more kilowatt-hours per kilowatt of system capacity," is primarily a sales job, but the engineer can and should make a definite and valuable contribution. Getting more kilowatt-hours per kilowatt of system capacity means an intensive development, requiring that power be furnished at lower than average prices for new uses and under conditions different from those we are familiar with. Attainment of maximum results will necessitate a thorough and accurate knowledge of the cost of service in each case. It is clearly the engineer's problem to determine cost of service, involving, as it does, an analysis of load factors and diversity of demand, investment required to serve, and so on, and he should make a careful study of the cost of serving each new class of business that comes up for consideration.

It is the function of the engineer to set up the engineering features of the service extension and installation rules. In many cases these have become very complicated and cumbersome and include requirements entirely unnecessary under conditions now existing. At this time the engineer can very properly review this entire situation with the purpose of simplifying the physical conditions under which service is rendered and thereby improving our relations with our customers.

*The executive committee of the Engineering National Section has adopted the following major objectives toward which the work of the section should be directed:*

*More kilowatt-hours per kilowatt of system capacity.*

*More system capacity per dollar of investment*

*Definite advance planning of system development, and co-ordination of adjacent systems.*

*Comprehensive research in fundamental engineering problems of the industry, co-ordinated through the committees.*

*Better content and wider distribution of serial reports.*

*Study of, and when desirable, reports on national engineering issues affecting our industry.*

*Constructive co-operation in the national movement for standardization.*

*Greater engineering service to the industry through closer co-operation with the other national sections of the N.E.L.A.*

*Recruiting and training of adequate engineering personnel.*

The second objective, "more system capacity per dollar of investment," is the engineer's own problem. There appear to be particularly three methods of approach to this objective, as follows: Development of best practices in engineering through the activities of the engineering committees of the N.E.L.A.; definite planning of system development; research both in system designing and operation and in apparatus and equipment.

The advantages in planning system development where growth is as rapid as in our industry are self-evident, but have not been fully appreciated until quite recently. Comprehensive planning will include a study of the probable future load conditions in the territory served and an analysis of the earning power of the different parts of the system; it will determine the economic steps by which to increase capacity and the proper time at which to make additions to the system; it will determine proper proportioning of steam and hydro-electric generating capacity, useful interconnections and co-ordinated development of adjacent systems; it will bring out new operating problems to be encountered in future conditions of load and system capacity, thus permitting a thorough study and solution before they become acute, and it will make it possible for the engineer to keep his executives fully informed in advance as to financial requirements for system development and probable engineering and operating difficulties to be encountered as the load grows.

---

**Abstract of address presented at the annual convention of the Southwestern Division, N.E.L.A., Biloxi, Miss., April 3, 1928.*

Research in apparatus and equipment is of course primarily the job of the manufacturer. Nevertheless, the manufacturer cannot furnish adequate equipment unless the power engineer defines the conditions which must be met in operation, and the power engineer must co-operate in testing and trying out under operating conditions new developments in equipment which give promise. For example, circuit-breaker tests on actual power systems have been an invaluable aid in improving circuit breakers. Similarly, recent tests of transient conditions on transmission systems have furnished data most vital to efficient design of systems and equipment.

### Economy in Expenditures

The power industry will undoubtedly spend more money both for operations and for additions to plant during the next ten years than it has spent in any previous like period of time. In capital improvements alone it is quite reasonable to suppose that as much as ten billion dollars will be spent. The engineers will be responsible for specifying how these huge sums are to be expended. Furthermore, the exacting demands for the highest possible grade of service and the economic pressure to get the greatest possible value out of every dollar spent, as well as the more intricate engineering problems coming from the enormous amounts of energy to be handled and the vast networks of transmission and distribution required to handle it, will make the engineering problems of the future more complex than those of the past, so that both the magnitude and intricacies of the situation will make it necessary that particular attention be given to the recruiting and training of an adequate engineering personnel to handle them.

The knowledge now available on the engineering problems of the power industry, if utilized by engineering talent of high grade, should make possible a future development far more consistent than that of the past, with a correspondingly lower unit cost of plant and of replacements for obsolescence. A more systematic development, based on better understanding of the problems of the future, will prove adequate to meet the conditions imposed by more exacting service requirements, greater economic pressure and larger volumes of energy to be handled.

### New Type of Engineer Needed

I believe it is fair to say that at the moment there is considerable opportunity for improvement in the organization of the engineering forces of member companies and in the quality of engineering achievement. In the past many engineers of above the average in ability have been diverted to executive positions because of the greater necessity of filling such positions effectively, with the result that there is a shortage of high grade engineering talent in our industry. This means that more attention should be given to bringing the best engineering graduates into the industry and more interest should be taken in the courses given in the engineering schools, in order that the graduates may be better fitted for the work they are to perform.

The development of the huge power systems now in operation and growing at a rapid pace have changed the character of engineering talent required. Whereas not so many years ago the power system engineer was confronted mainly with the details of making the different pieces of apparatus work, he now faces the far broader problems of developing a co-ordinated system that will deliver an even higher quality of service than has been accomplished in the past and will show the greatest possible return for every dollar spent.

The job of the power system engineer today starts, of course, with getting solutions to his physical problems, but it by no means ends there. Following the solution of the physical problem there must be an economic analysis of each situation, including comparison of the present and future capital requirements, annual over-all costs, both in operating expense and fixed charges on investment over a period of years; extent of replacement of existing equipment in each case and justification therefor, accuracy of the assumptions made and possible effect on results as actual conditions develop that are at variance with them. The situation must be studied from the executive, commercial and public relations viewpoints, so that the engineer must go beyond the realm of the scientific into that of the business man. And just to the extent that he is able to understand and anticipate the executive's judgment as drawn from all of these viewpoints, to exactly that extent does he become a more valuable man and put himself in line for bigger things.

### Conclusion

In conclusion, it is desired to leave two thoughts for consideration:

1. The industry will spend more money in the next ten years than in any past like period. It will be called upon to meet more exacting service requirements than ever before, and will be under greater economic pressure so that more careful attention will have to be given to every dollar spent. These are the engineer's problems and they are more difficult than those which have confronted him in the past. There is, therefore, an important executive problem to be worked out in recruiting and training the necessary engineering talent and in providing an organization to enable it to function adequately.

2. To meet these more exacting requirements the engineer must be developed into a "scientific business man." His job starts with getting solutions to physical problems, but it by no means ends there. He must be a good business man, a salesman, a diplomat and "must play with the teams" if he is to deal successfully with those men with whom he must deal if his plans are to materialize. Just to the extent to which the engineer understands and anticipates the executive judgment, which must be based on organization, commercial and public relations viewpoints, as well as on engineering, to exactly that extent does he become a more valuable man to his company.

---

## Ovens Found Best for Drying Electrical Apparatus

By T. A. Converse
*Local Manager American Electric Service & Maintenance Company, Troy, N. Y.*

EXPERIENCE indicates that in drying out water-soaked motors, control apparatus, etc., the work should be done by baking and redipping in preference to drying out by electric current circulated through the windings, except where emergencies preclude the oven method. Our tests show that when dried out internally by heating up the windings through current application there is a tendency to char the insulation and to cause deterioration of the external insulation on the coils. We have also found it necessary to redip the winding in insulation varnish to bring it back to the standards that existed before the winding was damaged.

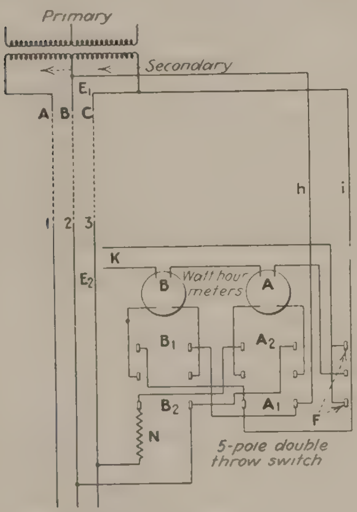
In the late Vermont flood we had a variety of apparatus to dry out, including both alternating and direct-current motors, transformers and other equipment. Our method was the same in all cases, that is, the apparatus was disassembled and the windings were placed in an oven and baked for 72 hours at 250 deg. F. The apparatus was then tested for breakdown and resistance, and if in good condition the coils were dipped in varnish and the apparatus rebaked at the same temperature for 48 hours. This method was entirely satisfactory and we believe that if the apparatus to be dried is not too large it pays to follow this plan rather than to dry out by excess currents and finish with surface coats of varnish.

# Errors from Potential Transformer Leads

By G. A. Collins

*San Joaquin Light & Power Corporation, Fresno, Calif.*

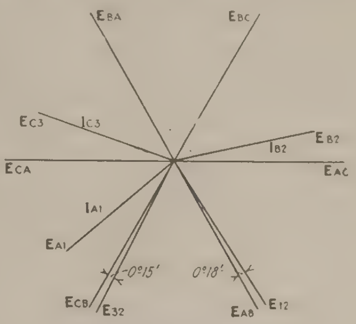
Long leads in the secondaries of potential transformers, unless the size of conductor is larger than ordinarily used, introduce appreciable errors in the registration of watt-hour meters. With a secondary burden consisting of two watt-hour meters and a directional relay potential coil a 300-ft. run of 19-25 stranded cable will introduce a phase shift of between fifteen and twenty minutes. This phase angle, in the case of an inductive secondary burden on the potential transformer, is in the same direction as the phase angle of the potential transformer and the two add in their effect on the accuracy of the watt-hour meters. If in addition to the two watt-hour meters and relay potential coil a non-inductive burden of the order of 200 volt-amperes is added to one of the phases its potential will be lowered about 2 per cent and that of the other phase raised somewhat. In this case considerable error is introduced by the voltage drop and there is also an appreciable phase shift.



*Wiring arrangements for measuring potential drop and phase angle of leads*

*N* is a resistance equal to that of the leads *h* and *i* from the potential transformers to the switchboard. *K* is a source of current for the series elements of the two watt-hour meters.

The watt-hour meter method of testing instrument transformers can readily be adapted to measuring the phase angle and potential drop in the secondary leads of potential transformers. The accompanying wiring diagram indicates the connections for measuring the potential drop and phase angle of leads *B*-2 and *C*-3 for phase *BC*. The resistance and reactance of the leads *h* and *i* should be kept low by using a good-sized conductor, about No. 10, and twisting or tying the two together. The two jaws, *F*, of the double-throw switch are shorter than the others, so that the current circuit, *K*, is opened in advance of the two potential circuits. This eliminates any error that would result if the two potential circuits did not open or close at exactly the same instant owing to slight differences in the lengths of the potential switch jaws.



*Phase-angle relationships as determined in test*

With the current in the series coils of the watt-hour meters in phase with the potential *BC*, two sets of readings are taken; first, with the switch in the position $A_1\ B_2$, the revolutions of the meters *A* and *B* being designated $A_1$ and $B_2$, respectively, and, second, with the switch in the position $A_2\ B_1$, the revolutions of *A* and *B* being designated $A_2$ and $B_1$. Then

$$\frac{E_1}{E_2} = \sqrt{\frac{A_1\ B_1}{A_2\ B_2}}$$

which is the ratio of the voltage at the transformer terminals to that at the switchboard.

To get the phase difference of $E_1$ and $E_2$, the current in the series coils of the watt-hour meters is made to lag behind the potential *BC* and another set of readings is taken, from which

$$\cos\ (\theta + \alpha) = \cos\ \theta\ \frac{E_1}{E_2} \sqrt{\frac{A_2\ B_2}{A_1\ B_1}}$$

$\theta$ is the angle by which the current in the series coils of the meters lags behind the potential *BC*, $\frac{E_1}{E_2}$ is the ratio, found in the first test, of the voltage at the transformer terminals to that at the switchboard, $A_1$, $A_2$, $B_1$, $B_2$ are the readings of the two watt-hour meters and $\alpha$ is the difference in phase between $E_1$ and $E_2$. This form of the phase angle formula is convenient for logarithmic calculation and leaves no question as to the sign of $\alpha$, or need of further tests to determine it. $E_2$ leads $E_1$ if the sign of $\alpha$ is positive.

To check the accuracy of the method a set-up was made, $\frac{E_1}{E_2}$ and $\alpha$ determined by the watt-hour meter method of test and the results checked by calculation. The burden across each of the two phases (1-2 and 2-3) consisted of two watt-hour meters and a directional relay potential coil. The resistance of the lead *A*-1 was 0.479 ohm; *B*-2, 0.492 ohm, and *C*-3, 0.472 ohm. The current in leg *C*-3 was 0.463 amp. and lagged 79 deg. 45 minutes behind potential $E_{CB}$. The current in leg A-1 was 0.518 amp. and lagged 79 deg. and 17 minutes behind potential

COMPARISON OF RESULTS OBTAINED BY TEST AND CALCULATION

| | Phase Angle | | $\frac{E_1}{E_2}$ | |
|---|---|---|---|---|
| | Phase *AB*, Minutes | Phase *CB*, Minutes | Phase *AB* | Phase *CB* |
| By test | +19 | +18 | 0.9990 | 1.0023 |
| By calculation | +18 | +15 | 0.9993 | 1.0026 |

$E_{AB}$. The phase sequence was $CBA$, potential $AB$ leading potential $CA$ 120 deg., and potential $CA$ leading $BC$ 120 deg. Both phase voltages $AB$ and $BC$ were 120.5.

## Portable Transformer Bank Aids System Changeover

By Maurice D. Smith

DURING a recent system changeover from delta to Y secondaries it was often found necessary to install a bank of transformers temporarily in order to boost the voltage at certain points. The transformers were installed either on a pole or in an inclosure and were in service for only a short time, the period of operation varying from three days to a week, depending upon the amount of related work to be done on the distribution circuits and at the customer's premises.

*Transformer bank permits rapid shift from delta to Y secondary distribution system*

In order to provide continuous and adequate service, it was felt that the expenditure was justified, but that the time required to install, dismantle and shift it to a new location had a tendency to retard the changeover progress. The possibility of using a bank of transformers permanently installed on a trailer was then studied and it was found to be the most economical and convenient means of supplying emergency and temporary service.

A 2-ton, completely inclosed electric truck which had been in service for many years and was to be retired was converted into a trailer at a small expense. It was equipped with three 100-kva., single-phase transformers connected as shown in the accompanying illustration and offered a flexible outfit. The primary cables enter the trailer through the roof, going first to a set of primary cutouts, which are fused for 100 amp. each, and then to the transformers. A pothead is installed in the primary neutral so that the neutral may be opened for the closed delta connection and closed for the Y connection. By throwing three two-pole and one three-pole, double-throw switches either a delta or a Y connection can be made. Conductors of 800,000-circ.mil cable are brought from the transformers to the switches and from the switches to a terminal board. Here the cables to the network, which enter the trailer through the floor, may be shifted either to the delta or to the Y connection in a short time. A color scheme is used to mark the delta and Y connections in order to prevent the operator from making a false connection. This arrangement so speeded up the work that it enabled the completion of a large project ahead of schedule.

## Computing Compensator Settings for Automatic Regulators

FIRST ARTICLE

By V. W. Palen

IT IS the author's purpose to outline quite completely in this series of papers, of which there are five, the steps in the method used by an Eastern electric company for obtaining compensator settings for its voltage regulators. The engineering division of this particular company supplies the operating division with such computed settings in advance of all major feeder changes. In relatively few cases has it been necessary to substitute experimental settings for the theoretical ones computed beforehand.

Take the case of a single feed. The load center is located quite definitely through a careful study of the maps showing all of the transformers supplied from the primary in question. Once the load center location is determined, the resistance, reactance and impedance of the primary from substation to load center must be computed.

CHARACTERISTICS OF UNIT LENGTHS OF CONDUCTORS

| Type of Primary | Ohms Resistance | Ohms Reactance | Ohms Impedance |
|---|---|---|---|
| 1,000 ft. of 350,000-circ.mil underground cable | 0.0345 | 0.0369 | 0.0580 |
| 1,000 ft. of 250,000-circ.mil underground cable | 0.0431 | 0.0379 | 0.0570 |
| 1,000 ft. of No. 2/0 overhead wire.......... | 0.0790 | 0.1320 | 0.1540 |

In the case given in the accompanying illustration the load center is 4,000 ft. from the substation. Using the data in the accompanying table the resistance, reactance and impedance from substation to the load center are as follows:

| | | Ohms Resistance | Ohms Reactance | Ohms Impedance |
|---|---|---|---|---|
| (AB) | 1,000 ft. of 250,000-circ.mil. underground cable.................... | 0.0431 | 0.0379 | 0.0570 |
| (BC) | 3,000 ft. of No. 2/0 overhead wire..... | 0.2370 | 0.3960 | 0.4620 |
| (AC) | Total........................... | 0.2801 | 0.4339 | 0.5190 |

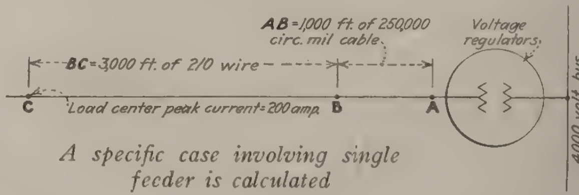
Since the primary current at peak load is 200 amp. and since the ratio of the current transformer is usually 20 to 1:

$$\text{Resistance Drop (AC)} = \frac{0.2801 \times 200}{20} = 2.801 \text{ volts}$$

$$\text{Reactance Drop (AC)} = \frac{0.4339 \times 200}{20} = 4.339 \text{ volts}$$

$$\text{Impedance Drop (AC)} = \frac{0.5190 \times 200}{20} = 5.190 \text{ volts}$$

The compensator on this feeder, therefore, is set as nearly to the values above as is possible.



AB=1,000 ft. of 250,000 circ. mil cable
Voltage regulators
BC=3,000 ft. of 2/0 wire
C
Load center peak current=200 amp.
B
A
4,000 volt bus

*A specific case involving single feeder is calculated*

In the papers to follow the author will take up the computations for single-loop, double-loop and triple-loop circuits. In the last paper of the series various types of compensators and methods of applying definite settings to each will be described.

# Low-Cost Rural Construction

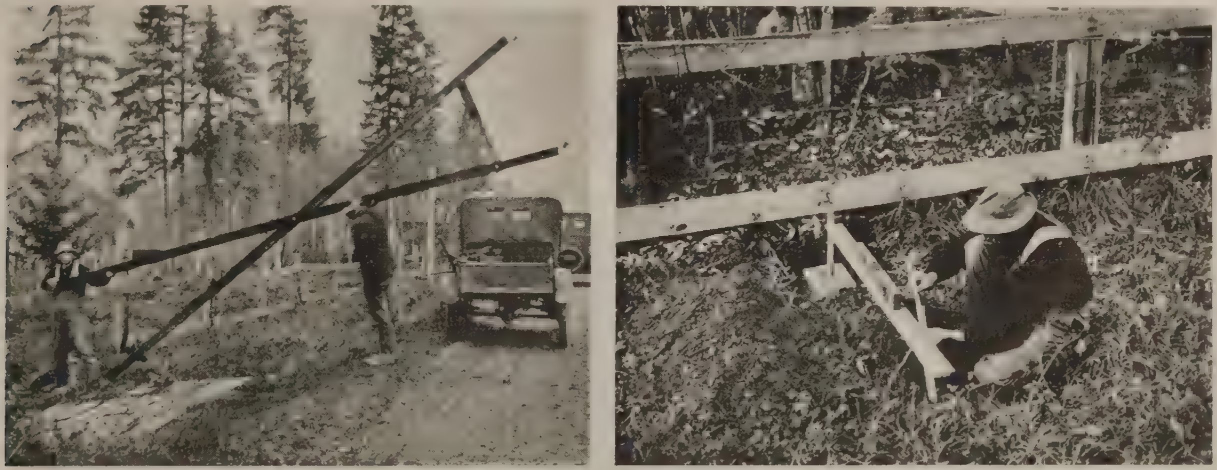
### Lightweight X-frames, utilized to provide service at minimum cost, prove practical. Single-phase rural lines constructed for $333 per mile

By George W. Kable
*Agricultural Engineer*

A FLEXIBLE, scissors-like frame made of 2x4-in. timbers and hinged at the base to 1-in. iron pipes set in concrete blocks replaces the customary pole in an unusual type of 2,200-volt rural line construction used by the Young Electric Company near Sherwood, Ore. This type of support makes possible the construction of a single-phase rural line at a cost of $333 per mile. It was evolved by D. S. Young five or six years ago and is not entirely an untried experiment, one such line having been in service for more than four years. Some of the advantages claimed for the line are: 50 per cent reduction in farm line construction and maintenance cost; a safe line complying with regulations; no pole climbing; a two-man line crew at farm wages; no rotting off of poles, and no guy wires crossing roads.

The owner and manager of the Young Electric Company is a farmer. Six years ago he purchased about 6 miles of rural distribution line having a bad financial reputation and threatened with paralysis. In endeavoring to maintain and extend his lines and give reasonably good service, the owner was forced to measures of economy that have stimulated originality. For instance, he reads meters once every three months, presents the bill on the spot, discusses any difficulties or contemplated equipment the user may have in mind, and in 90 per cent of the cases collects the bill. The meter book, including detachable bill form, comprises the entire bookkeeping system. These economy measures, including the flexible frame line construction, have resulted in reductions in first cost and overhead sufficient to permit service in territory which under a more costly system would probably be without electricity for many years.

All of the distribution lines of the company are single-phase, 2,200 volts. The system at present consists of two separate units embracing 8 miles of pole line and 11½ miles of flexible frame construction. Power is purchased from two different companies and distributed to a total of 90 customers, mostly farmers. Sixty per cent of the load is lighting.

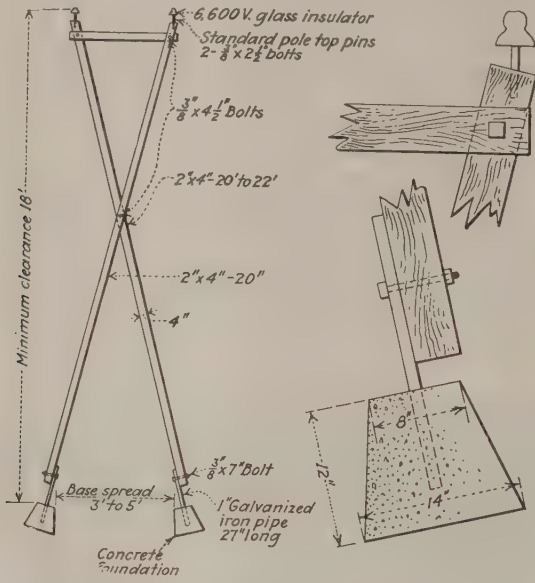


*Erecting one of the X-frames after wires are tied in and installing the pre-cast concrete footings*

The distinguishing feature of the flexible line is the frame. Intermediate frames are made up of two 2x4's, and anchor frames of 3x4's bolted together near their centers with ⅜-in. bolts. A cross-member is bolted near the top as shown in the accompanying illustrations. The frame is bolted to two 1-in. iron pipes embedded in pre-cast pyramidal concrete blocks. Anchor frames are placed at intervals of about one-quarter mile, at road or line crossings, where transformers are hung and at points where the line changes direction. Frames are anchored to concrete dead-men through anchor rods, strain insulators and ¼-in. guy cable attached to the frame cross-member near the top.

There are no lateral guys on the frames. On slight curves the frames are stiffened by vertical tension members which carry the side pull to the foundation blocks. On sharper curves a third anchor block is used, causing the resultant forces to still fall within the base of the frame and make it self-supporting. Where service leads run from a frame, the transformer is hung to one side of the center of the cross-member to balance the pull of the service wires. No attempt is made to place anchor blocks on the same level. On hillsides one leg of the frame may be 6 or 8 ft. longer than the other.

In erecting the line the cross-members are bolted together on the ground, the wires tied in and the frame raised in the manner shown in one of the accompanying illustrations. In this way two men will erect one-half mile of straight line completely in one day after the precast concrete base blocks have been placed and the material delivered to the job. Costs for building 9 miles of line in 1925 are given in the accompanying table.



*Dimensional details of X-frames for supporting 2,200-volt rural line*

COST DATA FOR X-FRAME RURAL LINE CONSTRUCTION

| | |
|---|---|
| Anchor rods | $51.50 |
| Bolts | 68.08 |
| Cable | 29.85 |
| Cement | 119.00 |
| Copper (Nos. 6, 8 and 10) | 887.24 |
| Cutouts | 20.00 |
| Clevises | 22.20 |
| Gravel and sand at $2.75 per yd | 75.00 |
| Guy clamps | 41.26 |
| Glass insulators | 50.52 |
| Eye bolts | 17.15 |
| Strain insulators | 53.70 |
| Lumber at $18, $20 and $22 per thousand | 262.45 |
| Pole top pins | 120.50 |
| Anchor pipe | 169.16 |
| Washers | 16.74 |
| Reinforcing for anchor blocks | 10.00 |
| Total | $2,014.35 |
| Plus 10 per cent | 201.43 |
| Total material cost | $2,215.78 |
| Total labor cost | $713.30 |
| (Including clearing right-of-way, assembling materials, cement work at 60 cents per hour, digging anchor holes at 20 cents each, and two men erecting line at $5 and $4 per day) | |
| Insurance | $39.81 |
| Freight | 35.00 |
| Total cost of line | $3,003.89 |
| **Total cost per mile of line** | 333.76 |
| **Material cost per mile** | 246.20 |
| **Labor, insurance, freight, etc., per mile** | 87.56 |
| Following are total costs for individual frames erected in place and including all labor and material except that for clearing right-of-way and for copper: | |
| Intermediate frames | $6.00 |
| Light turn and service drop frames | 6.90 |
| Heavy turn frames | 9.00 |
| Transformer and intermediate anchored frames | 10.05 |
| Dead-end frames | 12.45 |
| Transformer and heavy turn frames | 12.75 |

Mr. Young has not constructed his flexible line without criticism. At first thought the 2x4-in. frames seem dangerously flimsy and the hinged base a travesty on the creosoted pole. Such a radical change must also offend the eye of many who have grown up with pole lines. The seeming unsightliness of the frame line diminishes, however, as the novelty wears off.

The Oregon Public Service Commission, while not having passed formally upon this type of construction, has the following to say regarding it: "This type of construction was called to our attention previously through an informal complaint, and a field inspection was made by our engineering department. . . . Sections of line using this class of construction were found to be giving satisfactory service after many years. Will further advise that additional study of this matter indicates that in so far as construction requirements prescribed by this commission and contained in the Na-

*Inexpensive rural line construction used in a farming section*

*Transformer structure with offset to balance service wire pull*

*Self-supporting angle structure using simplified design* tional Safety Code are concerned, this type of supporting structure meets all rules and regulations prescribed for rural line construction."

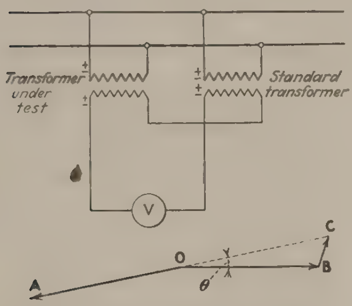
Obviously, the greatest use which the frame construction might be expected to serve would be for the secondary distribution lines and perhaps for private farm extensions where low first cost is desirable and unskilled workmen are available. At least it offers a possibility worth considering in rural line extension programs.

## Measuring Instrument Transformer Characteristics

By Carl W. Evans
*University Station, Tex.*

IN THE cases of utilities in which the number of necessary instrument transformer tests is small it is not generally economical to purchase elaborate testing equipments for this work. To such companies the following method of checking the ratio and phase-angle characteristics of current and potential transformers will be of interest inasmuch as the only special equipment required consists of standard potential and current transformers and low-reading voltmeter and ammeter.

For testing a potential transformer the connection shown in the accompanying illustration is used. It will be observed that the voltage of one transformer is in opposition to the voltage of the other. The voltmeter, $V$, indicates the vectorial difference between the two voltages. Because all alternating - current voltmeters are of the electro-dynamometer type, the voltmeter will not indicate which of the two is the higher voltage, but this can be determined by measuring the voltage of each separately. If the voltage of each transformer and the voltage indicated by the voltmeter are plotted to scale vectorially, the result will be a closed triangle, as shown. The vector $OA$ is the voltage of the standard transformer; the vector $OB$ is the voltage of the unknown transformer, and $CB$ is the vectorial difference of the two, which is the voltage indicated by the voltmeter. From this information it is possible to determine the characteristics of the transformer under test. If $R_s$ is the ratio of the standard transformer, then the ratio of the transformer under test is given by the formula:



*Simple ratio and phase-angle test for instrument transformers*

$$R_x - R_s \frac{OB}{OA}$$

where $OB$ and $OA$ are the voltages, respectively, of the unknown and the standard transformer secondaries.

The phase angle of the transformer under test, as compared to the standard, is the angle between $OB$ and $OA$ reversed; that is, between $OB$ and $OC$. Since the values of $OA$, $OB$, $OC$, and $BC$ are all known, the angle may be determined very easily from the trigonometric formula:

$$\phi = \cos^{-1} \frac{OB^2 + OC^2 - CB^2}{2 \times OB \times OC}$$

In the testing of current transformers the procedure is exactly the same, the current transformer under test and the standard transformer, excited from the same primary source, being connected in such a manner that their secondary currents are in opposition and the resultant current of the two being measured by a low-reading ammeter. The same formula may be used, the only difference being that the values substituted are currents instead of voltages.

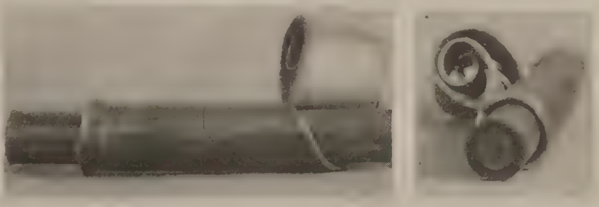
The phase angle determined by this method is the angle between the secondary voltages of the standard and the unknown transformer. It is impossible by this method to determine whether the voltage of the transformer under test lags or leads the voltage of the standard transformer, hence it is not possible to correct the values found with the correction curves usually furnished with the standard transformers. When the characteristics of the standards are very nearly ideal, as they usually are, the error introduced by not correcting the readings with the correction curves is very slight. Only where a very high degree of accuracy is required, as in laboratory measurements, will the accuracy, obtained by the expensive equipment available, justify the additional investment.

## Proper Cutting of Lead Sheath Improves Cable Splicing

By John A. McHugh
*Assistant Engineer New York Edison Company*

IT HAS been found that in the preparation of paper-insulated, lead-covered cable for splicing two troubles arise which can easily be prevented: First, the lead is not always uniformly belled around the cable; second, the outer papers of the mill insulation are sometimes damaged, either in making the usual lateral cut through the sheath or in attempting to bell out the lead.

Both of these difficulties can be overcome by following an improved procedure for the preparation of the cable ends. A sharp knife or specially designed tool is used to scribe around the cable at the location where the lead is to be removed. A helix is then scribed from this point to the end of the cable. The lead is pierced at the outer end of the helix and grasped with pliers. By rotating the pliers in a manner similar to the operation of a can opener the lead is easily removed, as is shown in the accompanying illustrations. The radial tension applied to the lead in the operation produces an appreciable belling-out of the lead, sufficient to relieve electrostatic stresses in cables for moderate transmission voltages and to permit the easy introduction of metal foil for reducing the stresses in higher voltage cables. This feature can be noted in the illustration. It may also be observed that the marker tape under the cable sheath is not disturbed.



*Helical cutting back bells cable and protects insulation*

# Transmission by Cables

## High-voltage cables considered as commercial possibilities in power transmission. Costs and performances compared

By Dr. Richard Apt
*Director V. L. G. Cable Company, Berlin*

*That aviation will necessitate some change in American high-tension transmission practice is the opinion of Dr. Richard Apt, director of the V. L. G. Cable Company of Berlin, who is at present visiting this country, to study our cable system.*

*When asked by the* Electrical World *to comment on the outlook for high-tension cables suitable for American electric light and power conditions Dr. Apt made the following remarks:*

JOINTLY with friends in the German cable industry, Messrs. E. Hartmann, Duisburg; A. Geissler, Mannheim, and R. Halbreiter, Rheydt, I came to America for the purpose of personally familiarizing myself with the status of American cable technology and discussing with American engineers the problems which exist in cable technology and power transmission by cables.

Overhead circuits are exposed to a great extent to the influence of the weather, particularly storms and rain. It is true that it has been possible greatly to increase the mechanical and electrical strength of the insulators; nevertheless, to the open-air circuit there always adheres the disadvantage that it is subject to all influences, even to intentional interference. Industries in which continuous power supply is a prerequisite may therefore hesitate to permit their plants to be fed by an overhead feeder. To this must be added that it is practically impossible to run overhead circuits of high voltage in cities.

For exactly the same reason that satisfactory telephone communication only became possible when the telephone wires were in cables, development of high-voltage power transmission will also aim at underground distribution. An important factor leading to such a decision is the development of aviation. There can be no doubt that aviation will in a few years increase many times beyond its present status and that regular air lines, similar to our present railways, will run through the country. In Germany regular aviation service has already reached noteworthy proportions, and the development in this country, with its disproportionately greater distances, will undoubtedly be similar to that abroad. For aviation, however, high-voltage lines represent a great danger, and there will hardly be any means, for instance in the event of sudden fog, to render the existence of overhead lines noticeable to the flier.

The cable industry of the old world and the new has, on the strength of these considerations, most zealously promoted in the last few years investigations in high-voltage cable technology and in the manufacture of the cables themselves. Extremely careful examination and testing of the material, particularly of the paper and the impregnating substances, has led to great improvements and has rendered it possible materially to increase the specific disruptive strength of the insulation. The realization that punctures in cables are as a rule attributable to gas inclusions has led to special precautions in the manufacture of the cable and of the saturating substances in order to prevent the formation of gas bubbles within the active insulating material.

Hand in hand with the perfection of the manufacture went scientific researches. Cable works of even moderate size today possess laboratories equipped with transformers for voltages of from 500,000 to 600,000, so that all problems of high-voltage cable technology can be looked into and investigated.

An important step in advance was the building up of the so-called ionizationless cable by wrapping around the insulation a thin metal band or metalized paper according to Höchstätter. The idea that it is of primary importance to keep the insulating cover impregnated with oil has led to the interesting development of the Pirelli cable, in which a hollow conductor is kept constantly under oil pressure, and the New York Edison Company and the Commonwealth Edison Company of Chicago have installations of such cables rated at 132,000 volts.

In Germany cables for voltages of 100,000 have likewise been installed, and these with those in America leave no doubt, so far as the experts in problems of cable technology are concerned, that it is safe to carry out power transmissions for interconnected systems at 100 kv. with cables, and even an increase in the voltage to 200 kv. will hardly present insurmountable obstacles.

For these high voltages, of course, only single-conductor cables can be considered, even for alternating-current systems. Three-conductor cables would be too heavy. Moreover, the manufacture of the joints presents substantially greater difficulties than do joints for single-conductor cables. Moreover, the losses in the lead jacket of the single-conductor cables is not serious, especially if large quantities of energy are transmitted. The capacity of the cable network may also serve to improve the load factor. When the leading current becomes too great a compensation can be carried out by means of reactors.

### Cost No Handicap

Now, as regards the question of cost, undoubtedly a long-distance circuit made of cables will always cost more than an overhead line of the same voltage. It must be considered, however, that cables can be used with much larger cross-section for the single conductor than is possible with overhead lines, so that it will not always be necessary to raise the voltage in cables as high as in overhead circuits. It is evident, however, that the expenditure for the maintenance of the cable network and the supervising service will be much smaller than with an exposed overhead circuit. Likewise, the life of the cables, according to the experiences so far gathered, is much longer than that of overhead lines where it is necessary to replace the insulators after a lapse of years. If, therefore, the annual cost of the overhead line is compared with that of cables for each kilowatt transmitted, figures will be arrived at in many instances which render the use of cables thoroughly economical for large energy transmissions with high voltages.

My conviction, therefore, is that in the technology of the transmission of power the same development will take place as in telephony. It is true great problems have still to be solved, and to that end the experts in cable research in the various countries should co-operate with each other through a joint interchange of experiences and experimental results. Perhaps it would be a worth-while move if within the International Electrotechnical Commission a special committee were formed for studying these questions.

# Manufacturers Talk of Price Cutting

A group of selected letters from executives in different fields of electrical manufacture discussing who is to blame for the trouble in this buyer's market and commenting on the possibilities for reform

THE series of articles, editorials and letters from our readers which have been published in these pages since the appearance on Feb. 18 of the article by Earl Whitehorne entitled "Who Pays the Cost of Price Cutting?" have brought forth many letters of comment and opinion. Many manufacturers have related in detail experiences with buyers in which undoubted pressure has been applied to incite the salesmen to a competition in paring profits. They have been depressing both in number and in similarity because they evidence how far has gone this epidemic of profiteering by purchasers, through the gentle art of pitting one salesman against the other, taking advantage of the present mad competitive struggle for volume. Many, however, have testified to the price cowardice of sellers as the chief course of demoralization in the market place.

Also, many constructive ideas have been advanced. Some purchasing agents have stoutly contested the innocence of the buyer. Others have frankly argued for a broader recognition of the economics of purchasing and more ethical practices, as in the case of the article by the president of the National Association of Purchasing Agents printed in the ELECTRICAL WORLD on April 21. The following series of extracts from letters from the executives of manufacturing companies have been selected from the pile to present a cross-section of the sellers' viewpoint, as it has been reflected by readers of these articles:

---

## Destroying Price Levels for Allied Lines

*By a Manufacturer of Control Apparatus*

The present price-cutting situation in the electrical industry is serious. Unfortunately it appears that a good percentage of the manufacturers in the electrical industry, through necessity for more business, have more or less lost sight of their backbone. The average buyer, not taking into consideration the eventual effect, works on the manufacturer's pliant backbone and molds the same to his own desire. The result is an additional cut in price. In my estimation the manufacturer does not deserve any sympathy, but at the same time the situation is decidedly unfortunate.

A contributing factor to the bad price situation also lies in the lack of loyalty among the allied industries. The control manufacturer at the present time is up against a very serious situation imposed upon him by the motor manufacturer. While the motor manufacturer may maintain price on his motors, because of the longer discount which he is receiving from the control manufacturer, he has quite a bit of leeway in discount to play with, and does not hesitate at all to turn a good portion of this discount over to the buyer. Time and again the customer can buy our control cheaper through a motor manufacturer than he can buy from us direct and, this being the case, it naturally gives the control buyer a considerable leverage with which to lower the control manufacturer's price. We have known of some instances where the motor manufacturer was so hungry for business, or so anxious to do the buyer a favor, that he included the control apparatus in his motor bid at the exact cost of the control equipment to the motor manufacturer. Nor will the motor manufacturer listen to reason when this very bad situation is called to his attention, and it is his argument that since he buys the control apparatus, and pays for it, it is his privilege to do with it whatever he wants to. Technically he is correct, but practically he is making life miserable for the control manufacturer.

## One-Price Policy a Cure

*By a Bearing Manufacturer*

In my opinion the only practical solution is to encourage both purchasing agent and seller to submit closed quotations which shall not be subject to further change. If the manufacturer would stick by his first price the purchasing agent would be unable to gain anything by quasi-crooked purchasing methods. If the purchasing agent would at the outset state that he would not lend himself to such practices and insist upon the best price once and for all, then many of the complaints of which you very properly write would be avoided.

## Price Squeezing Impairing Quality

*By a High-Tension Equipment Manufacturer*

At the present time the situation is very bad from the viewpoint of the manufacturer, due to the fact that it is a buyer's market. The buyer is undoubtedly convinced of this fact and is taking undue advantage of this condition by telling the manufacturer just how much he will pay for the manufacturer's product. This condition is certainly a most unhealthy one because in the end it must result in disaster to the manufacturer who allows the purchaser to name his price for the equipment to be bought.

In consequence of this unfortunate situation manufacturers of all types of equipment of a certainty must be offering material of an inferior quality to that purchased during 1925-26, and in all probability, unless conditions change in 1928, this practice will be continued. In other words, this ceaseless sparring between the purchaser and the manufacturer is doing a lot of harm to both parties and in the end is going to result in more operating troubles, less responsibility on the part of the manufacturer and, what is worse, a decided inclination on the part of the manufacturer to slip out of his responsibilities whenever possible, due to the natural feeling that he was compelled to take the order at an abnormally low figure and he could not, of course, give the same service as would be possible if he secured normal profits.

## Temptation to Sell Low to Carry Overhead

*By a Pole Manufacturer*

There can be no question but what the interests of a buyer and a seller are exactly mutual. So far it has seemed impossible to find this common ground on which to meet. Nearly all buyers will declare themselves favorable to paying a price which includes a fair margin of profit, but their idea of arriving at that price seems to be to take the lowest bid.

We have noticed a decided tendency on the part of a great many purchasing agents to avoid making any investigation of producing, handling and grading methods and suspect very strongly that the reason for this is that they do not want to be forced to recognize that the commodity of one supplier may be superior to that of another for fear that it might handicap them in trying to hammer the price of the superior article down to the quotation made on the inferior.

The temptation to cut a price is, of course, always present. Volume has such a tremendous control of costs. When volume is slightly below the standard, then any orders secured at a price above primary cost help pay expense. It is very easy for one to argue himself into a position of preferring to have an order which helps pay expense, even though it does not pay its proportionate cost, than to refuse the order and not have that slight assistance toward operating cost and expense.

So far as I can see about the only thing to do is to continue to lay these problems before the buying public, hoping that in time it will have a favorable effect on those who feel that price is the only measure of value.

## Price Hammering on Special Jobs

*By a Power Equipment Manufacturer*

Realizing that it is hopeless to get the regular price after a price has once been cut on standard equipment, our policy is very fixed and definite; that is—maintain standard prices on standard equipment, and most of our responsible competitors do the same. Let me say that our standard prices show a very small margin between cost and selling price. What is recognized as sound business policy might recommend a greater margin, and this would indicate that an error was made in establishing the standard prices.

The jobs involving special equipment are usually large jobs. This prompts the purchaser to call in a number of manufacturers. They do not know what each one is quoting on, which creates an ideal situation for the purchasing agent, and he has not failed to take advantage of it. This hammering down in price has been gradual, but the seller is responsible for carrying it to its present extreme. If every manufacturer would quote prices that include a profit that he knows is necessary for a healthy condition of his business and refuse to take orders that only help to pay the factory overhead expense the business would divide itself among those who contribute most to their particular division of the industry or in proportion to the extent to which they contribute. This, I believe, will be brought about when both buyer and seller understand the present situation and see where it is leading.

## Most Purchasing Agents Absolutely Square

*By a Lighting Equipment Manufacturer*

Our experience has been that not much of the temptation for price cutting is due to any desire of the purchasing agents of large buyers to keep us from a legitimate profit. The purchasing agent is more concerned in a fair price, coupled with quality of goods and prompt deliveries.

We find that the purchasing agents of large buyers are absolutely "square" and willing to see us make a legitimate profit. They study their jobs and know what is a fair price and investigate the ability of their source of supply to serve promptly. There are still a few of the "old school" who feel a day's work well done only when they have lied to a bunch of salesmen, thereby keeping their companies from earning a legitimate profit, but that type is fast dying out or being placed in other positions where they are not so harmful to their employers. In the selling field the word soon gets around of such unethical purchasing agents and many good stories could be told of how they were cured.

Most of the trouble we have with price cutting in our own line is among the manufacturers' and distributors' salesmen. This practice is more and more becoming a thing of the past and will only be cured when all of us finally sell every one of our salesmen and distributors' salesmen on the fallacy of such a thing.

## Lump Sum Bid Unethical

*By an Instrument Manufacturer*

For many years it has been my opinion that one of the greatest impediments to the general building up of the industry has been the policy of the public utilities to resort to the "lump sum bid."

A large part of our sales activity has been directed toward breaking down this unfair method of purchasing, and I am glad to say that we have had considerable success. In my opinion it is a plan that cannot successfully withstand publicity, not only because of the ethics implied but because the policy tends to throttle development by stifling incentive on the part of the so-called independent manufacturers to develop and continually better devices they now manufacture. I think it is demonstrable that most of the development to which I refer has been contributed by aggressive independent manufacturers who are specialists operating under healthy and normal competitive conditions.

## Sliding Scale and Reciprocity

*By a Controller Manufacturer*

We suffer from the evil that you refer to, although perhaps to a lesser degree than the majority of electrical manufacturers, as we sell on a rigid policy of adhering, without deviation, to our established prices.

There are two other phases of merchandising electrical apparatus that have crept in during the last few years that I feel are detrimental to the business. One is the practice of establishing a sliding scale of discounts, a system of giving large purchasers preferential discounts on account of the potential buying power of these big customers, and additional quantity discounts worked out on a sliding scale, paid in the form of rebates at the end of the year. Any manufacturer, of course, expects to make a certain over-all profit on his products, and in order to give big discounts his list prices must be based accordingly. The customer of small purchasing power consequently pays an excessive price for the apparatus that he buys and the additional profit made on these sales helps the large and powerful purchaser to obtain his goods at a discount.

The other condition that we refer to is the use of reciprocity to coerce purchasers to buy electrical equipment. This is a method of commercial warfare against which the small manufacturer has practically no defense, and the ultimate outcome, if the buyers of electrical equipment do not offer strenuous resistance, would be to eliminate the small electrical manufacturer who does not have big tonnages of steel and other commodities to place. The business of this company has suffered to a considerable extent from the reciprocity pressure, as a number of good-sized orders which were about to be placed with us have been diverted to the large manufacturers due to threats on their part to cease buying from the customer unless the orders were placed with them.

## Too Much Salesmen's Gossip

*By a Pole Line Hardware Manufacturer*

Most manufacturers are hard losers and are more or less jealous of their competitors and will take the business at less than their cost merely to keep their competitor from receiving it.

We do not believe that the manufacturers who are selling a competitive line are close enough that they can sit down and talk over their difficulties without the conversation being broadcast.

The manufacturer pays too much attention to salesmen's gossip about his competitor cutting prices, but if the competitive manufacturers were so lined up that they could discuss costs with each other, I believe a lot of the trouble would be eliminated.

## Untrained Salesmen a Weakness

*By a Manufacturer of Fans and Blowers*

The tendency today in our own industry is to have untrained men and place them out in the field. The result is their lack of real engineering ability, their lack of ingenuity in meeting the unusual situation, causing them to waver in their determination to sell at the right price, and consequently they phone the factory for a reduction in price, making their case as strong as possible with the factory that the competitors are cutting prices. Invariably, from investigations which the writer has made, the salesman either deliberately misrepresented conditions or he merely took the word of the buyer.

We feel that not much progress will be made until manufacturers take the pains and effort to train their men thoroughly so that when the buyer reports that the price is high they are in a position to analyze why their price is high and incidentally show the buyer that they should receive more money because they are furnishing more and better goods, or that they be permitted to omit items which will bring their price on the same basis. Until the manufacturers develop that critical attitude of mind in their salesmen very little progress will be made in any field where engineering is as much a part of the sale as the product.

## Fair Play Pays the Purchaser

*By a Line Equipment Manufacturer*

I have learned both directly and indirectly that when the purchasing department plays absolutely square with any manufacturer the buyer's interests, in the end, will be better taken care of than where the purchasing department resorts to the practice of always taking unfair advantage of the seller.

For example, a certain commodity has been sold for several months at a uniform price, but owing to reduction in price of raw material (and after the manufacturers' present stock is exhausted) this commodity will take a lower price. If, in the meantime, the manufacturer is asked for a quotation on this product by the purchasing department for a customer and this customer has always played fair with the manufacturer he will be "tipped off" that it will be policy for him to delay his purchase on account of reduction in price shortly to take effect. On the other hand, if the purchasing department has used sharp tactics in its buying, to the detriment of the manufacturer, it will be only too glad to "load him up" at the present high figure.

There is no question but that both parties are in a measure to blame, and I have contended all along that it is absolutely wrong for the purchasing department of the buyer to dictate to the manufacturer or seller at what price his goods should be sold. Unfortunately, the manufacturers are handicapped by present laws, while the purchasing agents can have as many conferences and discuss the buying end, with the sole idea of bringing down prices and playing one manufacturer against the other to accomplish this end, but in no way incriminating themselves.

## Product Prestige Proof Against Price

*By an Insulator Manufacturer*

Graybeards do not endeavor to use reason with the boy in love nor with the man at war—both actuated so highly by emotion or desperation—nor is one to be censured, under the modern code, if he burns up the parlor furniture to keep the kids warm if no other fuel is available. Thus, with tonnage (buying) off, say, 20 per cent and the Overhead boys appearing regularly at table for every meal, what have you except cut prices?

Tell me not in idle patter that business is not emotional largely—especially big business—when an Insull, a Morgan, a Mellon, continue domination because "I like the game." Did not Napoleon and does not Mussolini also like the same game?

If this thesis rings reasonably true, business is not different or better; it is simply surrounded with different trappings—check protectors, efficiency experts, units of millions instead of thousands, and, as of yore, the purchasing agent is simply a salesman on the other side of the fence or a salesman a purchasing agent with change of residence and both aping the Dutch and Indians on the Manhattan purchase, where both thought they had, and wondered if they had, put over a good deal.

Remember, the purchasing agent, in a seller's market, doesn't dare ask, "Is this your best price?"—the sales gent insults easily. So, in a buyer's market, the purchasing agent dares and does ask, and by the time this reaches the sales end it is amplified orally into a demand and visually into an ogre across the desk.

Constructively, I will say that I don't blame either side; that the most salutary movement among the large central-station buyers is the selection of engineers of purchase instead of purchasing machines (clerks). To an engineering mind, one need not get blue in the face trying to explain that the reason "Your price is high" on 60,000 bolts (insulators?) is that there are 50 different kinds of steel and methods of making bolts and a nickel steel heat-treated bolt put in bed with an O.H. mal-born bolt is an insult to bolts in general—and even hard on the nuts!

Finally, you may quietly confide to your friends that all this dilemma may be avoided by making and selling a product so blessed good that buying and using it is a pleasure not to be contaminated by "an extra 10 and two 5's."

Maxfield Parrish does it; Franklin Booth does it; Teague does it; Johannsen does it! Tarnation to the school or system that tends to squeeze all the poetry out of business as the present trend and régime does, with big syndicate headquarters on Broadway or LaSalle Street and robots screwing up nuts or turning handles in Texas, Oklahoma and Vermont!

## A General Code of Ethics Needed

*By a Wire and Cable Manufacturer*

What this industry needs is a code of business ethics—a list of rules applying to all branches of the industry in their relation to each other—a code drawn up by representatives of all branches and subscribed to by all of the members of all branches.

Salesmen and purchasing agents should have copies of this code so that when a salesmen calls on a P. A. he can ask and expect to receive from the P. A. treatment exactly in accordance with the rules and regulations of the code. And, conversely, the P. A. can refuse the salesman certain information by mentioning the fact that the giving out of such information would be at variance with the code.

In other words, we would all know how to conduct ourselves without fear of doing what is really right, as we have now.

---

# Galvanizing with Electric Heat at Gary

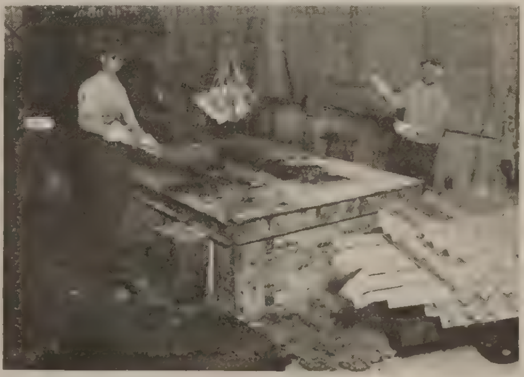
By Eugene A. Longgood

*Industrial Power Sales Engineer*
*Northern Indiana Public Service Company, Hammond, Ind.*

What is believed to be the largest electrically heated galvanizing tank in the world is installed in the Gary plant of the Walter Bates Steel Corporation, which fabricates steel for transmission line towers, substation structures, floor gratings and various other purposes. The tank is 30.5 ft. long, 48 in. deep and 22 in. wide and holds approximately 45 tons of spelter. Around it was built a furnace having three 135-kw. heating zones of equal length. Each zone contains three horizontal rows of heating elements, one above the other, on both sides of the kettle. The heating element—a continuous ribbon—is laced over the insulating supports, which form an integral part of the brick lining. Each zone is on one phase of a three-phase transformer bank and is controlled through a high-low switch. The temperature is automatically held at 820 deg. F. by pyrometers. The General Electric Company designed the furnace and furnished the electrical equipment.

The installation has a rated capacity of four tons per hour and a guaranteed consumption of 210 kw.-hr. per hour when galvanizing one ton per hour, 275 kw.-hr. per hour at two tons per hour, 345 kw.-hr. per hour at three tons per hour and 405 kw.-hr. per hour at four tons per hour. The standby losses were guaranteed not to exceed 90 kw.-hr. per hour when the kettle is covered and 140 kw.-hr. per hour when it is uncovered. The performance is about 15 per cent better than guaranteed. The minimum cost for electricity, which was obtained at the maximum production rate, was $1.50 per ton of steel galvanized; the average cost is $2. These figures are inclusive of energy used for maintaining the spelter temperature throughout the 24 hours of the day.

Power is supplied by the Northern Indiana Public Service Company under its demand schedule, with an off-peak clause. As the off-peak clause allows the use of 20 per cent of maximum demand during the peak, the fabricating part of the plant can work its regular hours.



*Electrically heated galvanizing kettle in plant of Walter Bates Steel Corporation*

Practically the entire output of this plant is galvanized and since this kettle was put in operation on May 10, 1927, production has run as high as 50 tons in twelve hours.

Automatic temperature control assures that the zinc is applied within the ideal heat range, resulting in a uniformity of coat that is highly desirable. This also saves spelter. Longer tank life is obtained because of the absence of oxidizing flames and due to the fact that the average temperature gradient in the wall of the pot is from 1,100 deg. to 820 deg. with electric heat, whereas it is about 1,600 deg. to 820 deg. with flame heating. The quality of the product and the cost per ton have been so satisfactory that this company has planned a second kettle, of double the width and longer, to take care of the increased tonnage requirements of its fabricated tower and pole business.

## Extending Investment List Strengthens the Markets

### Effect of recent New York legislation already evident in behavior of power and light securities

THAT recent legislation in New York State which widens the market for public utility securities has been effective and is likely to be still more so is indicated by the behavior of the security markets for these issues subsequent to the passing of the new legislation. Although not specifically designated, an examination of the securities coming within the provisions of the act indicates that a number of preferred issues and debentures of electric power and light companies, both operating and holding companies, have been legalized. Naturally this will influence the yield rate at which securities coming under the new legislation will be issued.

Much has been said of the rapid expansion in available investment funds of financial institutions. The number of individual trusts also has grown rapidly, and the funds available for investment in the assets of insurance companies have grown by leaps and bounds. As a consequence, there has been no little agitation for a widening of the legal investment lists of these institutions. Among the laws recently enacted relating to investments in New York savings banks one act makes provision that a savings bank under certain stipulated conditions may invest its assets in first or refunding mortgage bonds of designated electric, gas and telephone companies within the United States. It is added that a savings bank may not invest more than 10 per cent of its assets in electric or gas company bonds, or more than 10 per cent in telephone bonds.

### Definite Requirements Laid Down

While the new legislation does not make any blanket provision for investing in the securities of all power and light companies, it lays down definite stipulations with regard thereto. The corporation, for example, must have been in existence, as a rule, without default for eight years immediately preceding the investment; it must have outstanding stock equal to at least two-thirds of the bonded debt; it must have average yearly earnings for the preceding five years of at least twice average annual interest charges on its bonded debt during the period; it must have had net earnings of at least twice interest charges for one full year preceding the investment. The average gross operating revenue, moreover, must have been at least $1,000,000 a year for the five years preceding investment in the case of electric power and light companies. During each of these five years dividends of 4 per cent upon the minimum capital stock must have been earned or paid. With regard to the bonds themselves in the case of power and light companies, they must be part of an issue of at least $1,000,000 and the aggregate amount of bonds issued should not exceed 60 per cent of the physical value of the property.

New legislation relating to the investment of life insurance companies makes provision that domestic life companies may invest in the bonds, notes, debentures and preferred or guaranteed stock of any domestic corporation which has earned at least 4 per cent dividend on its capital stock during each of five years preceding. No insurance company, however, may invest more than 2 per cent of its assets in such securities or purchase more than 10 per cent of preferred stock of any one company.

The list of power and light company bonds coming under this new legislation relating to savings bank and trust investment has already been published in the ELECTRICAL WORLD, issue of April 21, page 838. While the new legislation deals with only one state, it involves a huge amount of investment funds, and it may be assumed that the step taken is just one step in the direction indicated.

## Selling Organization and Procedure at Topeka, Kan.

By W. A. Gregory

*Commercial Manager Kansas Power & Light Company, Topeka, Kan.*

TO INCREASE energy consumption by merchandising revenue-producing appliances in the most effective and economical manner the sales department of the Kansas Power & Light Company has divided the city of Topeka, with a population of about 56,000, into eight districts and assigned a salesman to each. Each salesman receives credit for all sales in his territory, whether they are made by himself or not. Compensation is at the rate of $75 per month plus 8 per cent on all regular sales. In "employee sales" campaigns the commission may be more or less than 8 per cent. Salesmen furnish and operate their own cars.

CREDIT POINTS DETERMINE MONTHLY AWARDS TO APPLIANCE SALESMEN

| **Sales** | Points |
|---|---|
| Credits—Cash sales (per $100) | 10 |
| Short-term contract (each month off maximum terms) | 1 |
| Down payment (each 50 per cent increase of minimum down payment) | 1 |
| Largest gross sales | 10 |
| Quota attained | 5 |
| Debits—Reverts (each $10) | 1 |
| **Conduct** | |
| Credits—Best general conduct for month (this to be judged by district manager and commercial manager and based on all activities of salesmen) | 6 |
| Debits—Absence from sales meetings (no excuses accepted) | 2 |
| Tardy to sales meetings (no excuses accepted) | 1 |
| Smoking in salesroom (during business hours) | 1 |
| Personal appearance (if it becomes necessary to mention same) | 1 |

Short meetings, which all salesmen, floor clerks and supervisors are required to attend, are held each morning at 8 o'clock for the purpose of imparting information, checking sales reports and giving special instructions. On Monday evening of each week there is a meeting attended by the utility service men and sales force to enable manufacturers' representatives to give them instructions and tips on their particular products. To every fourth one of these meetings the wives of the employees are invited and the affair becomes a sort of family party, with refreshments and some entertainment feature. Each month the commercial manager writes personal letters to the wives of the salesmen, telling them what appliances are being pushed, the records their husbands are making and explaining their work. These letters have been welcomed by the salesmen because they simplify the problem of fitting evening calls into their domestic relations. It has also been demonstrated that a wife's acquaintance with her husband's work is beneficial to all concerned.

Except for large appliances, salesmen make deliveries. Demonstrations of devices are made by the salesmen on their personal responsibility, the appliances being charged to them during the period of the demonstration. It is also the duty of the salesmen to see that devices returned from demonstration are put into clean and salable condition. List prices are maintained. Terms of payment vary with different types of merchandise, but the carrying charge is fixed at 6 per cent. All credit arrangements made by salesmen are subject to approval by the credit manager. Salesmen are empowered to make trade-in allowances on their own responsibility. Trade-ins are charged to a salesman's account at the price he allowed plus any service charges to put the merchandise in salable condition. Trade-ins are held in company stock and exposed for sale for 60 days. At the end of this period a trade-in is billed to the responsible salesman and he must remove it from stock within fifteen days. Commissions are not allowed on resale of trade-ins, but the difference between the resale price and the trade-in allowance, plus service charges, is paid.

To add incentive to the selling job a contest is conducted in which prizes of $25, $15 and $10 are awarded each month to the highest rating salesmen. Points are credited according to the accompanying schedule.

## Tungsten Lamps in Therapy

By M. Luckiesh
*Director Lighting Research Laboratory, National Lamp Works, Nela Park, Cleveland, Ohio*

Although radiant energy of various kinds is already serving well in the prevention and cure of diseases, many phases of radiation-therapy have not emerged from the twilight zone of knowledge.

We do know that much of the energy emitted by tungsten-filament lamps will penetrate to a considerable depth into the human body. On being absorbed most of this energy is converted into heat. This localized heating is achieved with less discomfort and often with greater safety and convenience with tungsten lamps than with hot towels or heating pads. Therefore, there are many legitimate uses for large tungsten lamps where such heating is desired. Perhaps medical research will establish many other uses of these lamps in the preservation of life and health.

PERCENTAGES OF TOTAL ENERGY EMITTED BY THE FILAMENT OF A 500-WATT MAZDA LAMP IN VARIOUS SPECTRAL REGIONS

| Special Region | Wave Lengths | Per Cent of Total Radiation |
|---|---|---|
| *Far and middle ultra-violet .. | (λ2,000 to λ 3,200) | 0.02 |
| Near ultra-violet ........... | (λ3,200 to λ 4,000) | 0.2 |
| Visible ..................... | (λ4,000 to λ 7,600) | 12.4 |
| †Near infra-red ............. | (λ7,600 to λ14,000) | 35.4 |
| Far infra-red ............... | (beyond λ14,000) | 52.0 |
| Total ....................... | (λ2,000 to limit) | 100.0 |

*Effective in rickets, etc.; not transmitted by ordinary glass.
†Transmitted by water (of which flesh is largely composed).

Progress in ultra-violet-therapy has been going on for years, but only recently has the public become interested. Much value of sunlight arises from the ultra-violet rays, particularly those which are not transmitted by ordinary glass (wave lengths shorter than λ3,200). Naturally this has led to a flood of inquiries regarding ultra-violet radiation emitted by tungsten filaments. Only 0.02 per cent of the total energy emitted by the filament of a 500-watt tungsten lamp is of wave lengths (shorter than λ3,200) which produce effects similar to those of one of the vitamines—preventing and curing rickets, for example.

The very small amount of this ultra-violet radiation that is emitted makes the tungsten lamps appear unpromising in this field of therapy at present. Obviously no special bulbs can increase the ultra-violet emissivity of the filament.

## Utah Sells 1,841 Washers in One Month

When the Utah Power & Light Company sold 1,841 washing machines during its eighth annual March washer campaign it broke not only all of its own previous records but established what is believed to be a record sale for the entire country. The slogan "A Copper Washer for a Silver Dollar," as in past years, played an important part in the campaign. Terms were $1 down and $5 per month. A quota of 1,000 machines was apportioned among the company's divisions, according to the number of customers in each. Employees other than the regular sales force were permitted to participate in the benefits of the campaign by the payment of $2 in cash for every prospect turned in which resulted in a sale.

*One of many store displays which aided in sale of 1,841 washers during month campaign*

Newspaper space was liberally used and special attention was given to store and window displays. The accompanying illustration shows rather an unusual store display which created interest. Sales during the March washer campaign of previous years were as follows: 1920, 1,711; 1921, 1,168; 1922, 1,191; 1923, 1,118; 1924, 1,148; 1925, 1,264; 1926, 1,012; 1927, 1,367. The total number of machines sold during these annual campaigns, including the 1,841 recently sold in March, 1928, now amounts to 11,820.

# High Voltage from Clouds

## Preliminary results from German endeavor to secure atomic breakdown from atmospheric electricity. Work to be continued

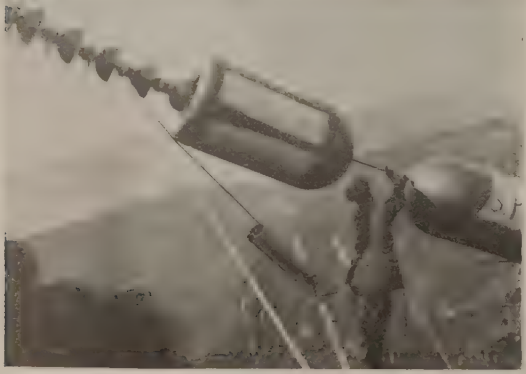
By Dr. Alfred Gradenwitz
*Berlin, Germany*

According to an account of preliminary tests given by Dr. Lange, assistant at the Physical Institute of the University of Berlin, at a recent meeting of the German Physical Society, he and his fellow workers A. Brasch and C. Urban expect by means of atmospheric electricity during thunderstorms to break up atoms during the coming summer.

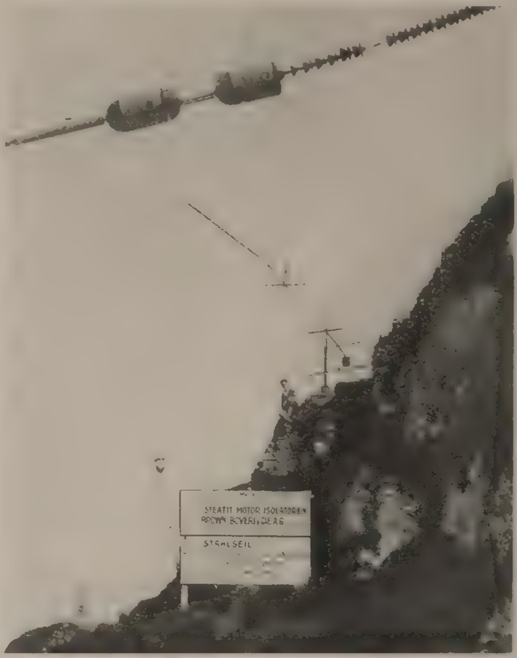
Accurate measurements of thunderstorm fields have shown the existence of field intensities up to a few hundred thousand volts per meter, so that a potential of, say, 5,000,000 to 30,000,000 volts is found to exist at a height of 100 m. If these potentials could be brought under control they would afford a means of producing extremely rapid corpuscular rays, of the same kind as those so far yielded by radium, though in much greater abundance.

The three experimenters found the most suitable place for installing their apparatus to be on the summit of Monte Generoso, a beautiful peak towering to a height of about 6,000 ft. near Lugano, which is noted for the frequency and violence of its thunderstorms. Also a mountain railway leading to the summit made this site an especially desirable location. The use of kites or balloons for collecting the electric charges was, of course, out of the question, such unstable systems constituting a serious danger to the experimenters. Only a stationary installation could be used and the three physicists chose a suspended network held by a messenger cable stretched out in a free span, antenna fashion, between two mountain tops.

Two experimental outfits were installed in succession, a smaller one for preparatory tests and a larger plant for what was intended for a definite test. The atmospheric electricity was collected by means of a network of wire comprising a multitude of small points, losses in leading in the collected charge being reduced to a minimum. Adequate insulation was provided at both ends of the messenger cable, which was given a radius of curvature as large as possible. The span adopted in connection with preparatory tests was 270 m. long, the network being situated at a height of 40 m. above the ground and insulated with 25 insulators. The lower part of the messenger cable, which served to lead the collected charges to the measuring instruments, was protected against corona losses by threading over it a series of hollow cylinders of very light material (thin galvanized-iron sheet) with a progressively growing diameter toward the ground. A potential of 3,000 to 5,000 volts was noted in normal cloudless weather, which, however, would grow to 70,000 volts (with several million amperes) whenever there was a thunderstorm passing over the plant. Two kinds of discharge were noted: First, those attending the passage of a lightning flash in the neighborhood; second, those characterized by a uniformly high potential and a uniform sequence of sparks not passing across the insulators.



*Corona cylinders on antenna at Mount Generoso*



*Antenna installation on Mount Generoso*

After conducting a set of preparatory tests with this small plant, a larger plant, with a span 760 m. long and a network stretched out at a height of about 80 m. above the ground, was installed. Voltage and other readings were taken from a small lightning-proof metal cabin, in which the spark gap installed below the corona guards could be controlled. The actual field intensity between the end of the antenna and the ground could not be ascertained, the clouds of ions produced by corona interfering with the normal distribution of field intensities at the very high potentials.

The installation of the larger plant was commenced in July, 1927, and, on account of local difficulties, could not be completed before the end of August. The main thunderstorm season was over, therefore, there being only one thunderstorm actually passing over the completed plant. This storm, however, unmistakably showed that very high potentials could be attained by the experimenter. The maximum sparking distance of the spark gap, which was 4.5 m., was readily bridged, the sequence of sparks during the period of maximum strength being about one per second. These discharges continued during 30 minutes and were remarkably constant. Actual experience with an auxiliary antenna and with remote thunderstorms showed that with such a dense sequence of sparks it was always possible to extend the spark gap to about twice its initial sparking distance before the limit of sparking was reached. Inasmuch, however, as such an increase in sparking distance was not feasible during thunderstorms a potential of only 2.3 million volts can be stated to have been measured, which corresponds to a sparking distance of 4.5 m.

The plant was left in position during the winter and is now to be extended so as to lend itself to measuring voltages several times as high. The potentials are so high, in fact, as to warrant the prediction that a definite success will be recorded in the endeavor to secure a breaking up of atoms.

## Letters from Our Readers

### *Suggests Salesman's Approach to Executives*

*To the Editor of the* ELECTRICAL WORLD:

I have read with a great deal of interest your editorial in the ELECTRICAL WORLD, issue of April 21, "The Salesman's Approach to the Executive." It occurs to me that the matter which you discuss has been improperly handled in the past due to the precise reasons as set forth. In my opinion more could be said as to the salesman's approach and I would suggest your consideration of the following facts for a further discussion of this subject through your columns.

In addition to submitting a business proposition, the salesman should bear in mind the fact that the executive does not think in terms of merchandising. He is interested only in technical matters pertaining to the operation of his property in order that his earnings may be adequate. When he is presented with a proposition which deals with earnings he at once becomes interested, and this interest can only be held through continuity of the same practice; that is, discussing earnings. Perhaps I can make myself better understood by assuming a salesman who is interested in selling 50,000 50-watt "Mazda" lamps to customers having an aggregate of 50,000 empty sockets. In order to secure the approval of this plan the salesman should point out to his executive that he is not particularly interested in the merchandising phase of the transaction, but is primarily interested in adding to the company's income, the potential income to be derived from this sale of 50,000 lamps. To set up his exhibit properly the salesman will point out to the executive that 50,000 50-watt lamps burning a lamp life average of 1,000 hours at 10 cents per kilowatt-hour will return $250,000, without adding one cent to capital investment account.

Likewise, a salesman contemplating a flatiron campaign should set up the same type of exhibit. He should, first of all, point out the potential revenue to be derived as a result of a certain number of irons sold. He probably is setting up a quota, in which case the quota figures should be used, the revenue to be derived based on the figures of the N.E.L.A., which would be considered authoritative. I am quite sure you see the point which I am making and which I should like to emphasize further with some personal experience.

A number of years ago, when I was connected with some of our operating companies, we were making figures on power requirements for certain coal mining operations which were at that time using their own power. We found it to be necessary in those pioneering days to present our proposition in a manner which would be understood by the coal operator. In other words, we had to reduce our sales to cost per ton of coal mined rather than cost per kilowatt-hour for electrical energy. This resulted in building up a very large volume of business. It was found at that time that other electric light and power companies were attempting to secure the same class of business on the basis of cost per kilowatt-hour. The result was that little headway was being made because the operator was not informed on such technical matters and, in fact, was not interested in the cost per kilowatt-hour. He only knew the cost per ton of coal mined.

We have the same picture in discussing a power proposition with a flour mill operator. It is absolutely impossible to make marked headway in this case if the cost per kilowatt-hour is discussed. The flour mill operator understands only the cost per barrel of output.

In conclusion, our executives, or our operators as you may choose to call them, are in about the same position so far as merchandising terms are concerned. It is difficult to secure their wholehearted and enthusiastic backing unless you can point out profits, and the profits which they are particularly interested in are those which reflect in the net earnings from operation. Merchandising profits are secondary.

C. J. EATON,
Vice-President in Charge of Merchandise Sales.
Middle West Utilities Company,
Chicago.

### *Conductor Movements Influence Line Design*

*To the Editor of the* ELECTRICAL WORLD:

We have noted with interest the editorial entitled "Conductor Movements Influence Line Design," which appeared on page 695 of the April 7 issue of the ELECTRICAL WORLD. Some of the values given seem to be in error, however, as we note there is a tension of 10,400 lb. on a No. 4/0 conductor. The minimum breaking strength of a No. 4/0 copper conductor, according to A.S.T.M. specifications, is in the neighborhood of 9,200 lb., while the minimum breaking strength of a No. 4/0 A.C.S.R. conductor is about 8,500 lb. We, therefore, question the tension of 10,400 lb. mentioned in the editorial.

Another point which occurred to us was the fact that there was a maximum throw of conductors of 4.07 ft. when used on a 150-ft. span. We are wondering whether this amount of throw was permitted by the sag in the conductor or whether an elongation in the conductor took place due to the high current suddenly thrown into the line which would be accompanied by a temperature rise.

DAVID T. WERNER.
New York, N. Y.

[The tension of 10,400 lb. mentioned in the editorial referred to represents the pounds per square inch allowed in the conductors and not to actual stringing tension of the conductor. However, there was one error in the figures given. It was stated that the conductor spacing was 4 ft. Although a number of tests were made at this spacing, the spacing was 18 in. in the particular case mentioned.

The sag of the conductor was approximately 1 ft. and the throw of 4.07 ft. was permitted partly by temperature rise due to the high current and partly by elongation of the conductor due to the very high stress set up by the violent repulsion of the conductors. Of these factors the latter was by far the most important.—EDITOR.]

# Digest of Electrical Literature

## *Hydro-Electric Development and Steam Equipment*

*Direct-Fired Powdered Fuel Boilers with Well-Type Furnaces.* — H. M. Cushing and R. P. Moore.—The 1926 extension to the Charles R. Huntley station of the Buffalo General Electric Company includes the addition of four 1,250-hp. boilers each with water-cooled furnace walls and 76 per cent economizer surface. The article describes the evolution of the furnace design, gives reasons for the selection of pulverized coal and the adoption of the direct-fired system and presents the operating results. Tests indicate unit efficiencies in excess of 85 per cent within the operating range of the equipment, which is from 125 per cent to 550 per cent of the rating of boiler and walls. The adoption of well-type furnaces for this station has enabled the utility to utilize coal with a low fusion temperature of the ash and no efforts are made to cool the ash which collects on the inner surfaces and gravitates in a liquid state to the well. The ash remains in a molten state until removed at desired intervals. This practice permits the use of the less expensive fuels and is said to represent an improvement in ash handling in pulverized fuel plants.—*Transactions of the American Society of Mechanical Engineers,* January-April, 1928.

*Some Economic Factors in Power Station Design.*—H. Boyd Bryden.—As a result of an analysis of design factors in connection with several generating stations, the author has concluded that the adoption of a 400-lb. operating pressure is desirable because of simplicity, ease of operation and cost of equipment. Conditions under which 1,200 or 1,500-lb. steam pressures may be attractive are anticipated and foreseen as desirably applicable to generating station work. On the contrary, 600-lb. pressures are discerned as offering few advantages. The author has reached this conclusion as the result of an examination of fixed charges, capacity and operated-hours factors. — *Mechanical Engineering,* May, 1928.

## *Transmission, Substations and Distribution*

*Some Experimental Results for Lightning Arresters.*—H. Rokkaku.—A comparative study of the various types of lightning arresters utilized in connection with high-voltage transmission circuits has been undertaken by the author. Observations secured through the use of the Braun tube are considered to offer the most informative data regarding the various styles. Arresters of the oxide film, air film, glass bead, carborundum and autovalve type were tested under similar conditions. It is concluded that the oxide film arrester has an ample discharge capacity, but there seems to be some uncertainty of action due to the change of material and displacement within the arrester cell. This type failed to indicate in these tests an operating reliability commensurate with that of the glass pellet and air film arresters. It is stated that any one of the arresters is subject to uncertainty of action due to the change of the materials with time, and that tests made with the Dufour oscillograph indicate behavior under single impulses which give satisfactory results.—*Journal of the Institute of Electrical Engineers of Japan,* March, 1928.

*Time-Limit Fuses.* — G. W. Stubbings. — It is the contention of the author that an exponential expression for the time-current characteristics of a fuse is based on an erroneous assumption and that it is hardly possible to secure more than an approximate value for the limiting current of a fuse by calculations based upon experimental values of the current for moderate time lags. A simple algebraic expression has been developed as a substitute for the more complicated exponential one and the curves have been derived to illustrate the simplified method used by the author for obtaining approximate time current accuracy. — *Electrical Review* (*England*), April 27, 1928.

## *Motors and Control*

*A New Starting Pulley.* — H. H. Schulmann.—A new starting pulley designed to permit the application of squirrel-cage motors where the use of such equipment has been restricted due to the heavy surges involved in starting, and more especially when starting against a full load torque, has been devised. It is stated that the use of this pulley makes the starting conditions of ordinary squirrel-cage motors and of double squirrel-cage motors quite as favorable as those of the slip-ring motor. It is also said that the simpler construction and the minimized attention requirements, better efficiency and power factor of the squirrel-cage motor may now be utilized without difficulty. The mechanism consists essentially of a centrifugal device, forming the necessary connections between the driver or driven parts. An important feature of this device is that the centrifugal weights which bring about the power transmission are not rigidly connected to the driving or driven parts. Cone-shaped disks move in an axial direction and are fitted on their outer surfaces with brake pieces of a material with a high coefficient of friction and good wearing properties. The inclosed form of this device permits its utilization under extreme dust conditions.—*A.E.G. Progress* (*Germany*), March, 1928.

## *Units, Measurements and Instruments*

*Design and Behavior of Magnetic Potentiometers.* — J. Ernest Shaw. — The possibilities in the use of the magnetic potentiometer for general electric measurements have led the author to discuss its application with particular reference to alternating current in networks that could not otherwise be easily measured, circulating current in various parts of machinery, reluctance of magnetic joints, ampere-turns on any assigned part of a magnetic circuit, exploration of leakage fields and similar applications. The theory and application have both been considered and direct-current and alternating-current measurements have been given special consideration. The design and the calibration of the potentiometer has also been considered and it is stated that it is always advisable to calibrate the potentiometer before making any measurements with the particular instrument with which it is to be used as considerable errors occur in calculating factors for a given circuit, the cross-sectional area and currents per centimeter are not uniform. The applicability of this device to the measurement of high-frequency current is pointed out. — *Electrical Review* (*England*), April 20, 1928.

*A Water-Level Gage of the Long-Distance Recording Type.* — E. B. Strowger.—The practical use of a water-level gage for hydraulic developments, utilizing the selsyn motor principle, is described by the author. The gage consists, essentially, of two selsyn motors. The position of the rotor of the transmitting device is controlled by a float or some similar means. The receiving motor operates a pen carriage which records, on a paper with suitable scaled divisions, the movements of the transmitting equipment. The motors are essentially induction motors with wound rotors excited from an alternating-current source. Conditions in the plant under discussion required close supervision of the headwater level because of the comparatively shallow intake existing at this development. — *Mechanical Engineering,* May, 1928.

## *Heat Applications and Material Handling*

*The Behavior of Metals and Alloys During Hot-Forging.*—W. L. Kent.—The research described in this article was initiated in order to investigate the forging properties of metals and alloys with a view to the application of a forging test as a measurement of their malleability at high temperatures. Many investigations have previously been made to determine this property by means of ordinary mechanical tests, but results given have not been entirely satisfactory. It is stated by the author that no mechanical test made may be considered satisfactory for this purpose, and that the only way in which malleability of a material may be determined is by actually rolling, drawing or otherwise working it under industrial conditions. It is, however, indicated in the present discussion that under certain circumstances useful information may be obtained regarding the variation in the working properties of a material with rise in temperature by combining the results of a special test herein described with that of a standard procedure. — *Engineering (England)*, March 16, 1928.

*The Autogenous Welding of Stainless Steels.*—The desirability, wherever possible, of subsequently heat-treating all stainless steel articles after the completion of the welding process is pointed out by the author. It is shown that all commercial welding involves heating the parts to be welded to a high temperature, usually approaching the melting point of the metal. This induces the formation of a coarse crystalline structure in the material in the region of the weld. In the case of the air-hardening stainless steel increased hardness is produced as a result of cooling in air from a high temperature. These two factors cause the resultant welded material to lack toughness. A comparison between various types of stainless steel and the difficulties encountered in the welding process have been covered in this discussion. Temperatures, electrodes material compositions, process requirements and general welding procedures, suggested in handling this material, have been covered by the author both for electric arc welding and for gas welding. —*Engineering (England)*, April 20, 1928.

### *Electrophysics, Electrochemistry and Batteries*

*Electrolytic Gas Generation Under Pressure.*—J. E. Noeggerath. — The electrochemical production of hydrogen and oxygen on a commercial basis furnishes gases of a remarkably high purity, but the installation of motor-driven compressors, by which the generated gases are forced into the customary steel cylinders, decreases the over-all efficiency of such a plant and makes close attendance a necessity. If the water dissociating cell is completely sealed the generated gas will, without additional effort, gradually reach any desired amount of pressure, and may thus be carried directly into its commercial containers. Certain difficulties have been experienced with the insulation between electrodes and ground to withstand such high pressure. Another problem was to find a safe and fully dependable means of keeping the oxygen and hydrogen separated. The paper describes construction of such equipment, generating gases at a pressure of 2,800 lb. per square inch, which gave excellent service. At this high pressure 3.25 kw.-hr. will produce 35 cu.ft. of gas of over 99 per cent purity. One of the greatest advantages is the exceedingly small floor space required, particularly when compared with gas generators operating at atmospheric pressure. — *Zeitschrift des Vereines Deutscher Ingenieure*, March 17, 1928.

*Some Comments on Dry Cell Service and Tests.*—C. A. Gillingham.—In a dry cell chemical depolarization takes place only while the cell is under load. Physical depolarization, such as the gradual rise of hydrogen bubbles, takes place both while the cell is under load and after load is discontinued. There are also shelf reactions, such as the slow dissolution of the zinc metal. The cell performs most efficiently, according to the author, when the severity of service is just light enough to allow perfect depolarization without passing beyond this point. The author recommends specific tests for each of the many types of dry cells, emphasizing the desirability of having the individual test conform as closely as possible to the actual service to which the respective type of cell is to be put.—*Report American Electrochemical Society*, April, 1928.

### *Telegraphy, Telephony, Radio and Signals*

*Quartz Radio Resonators.*—G. W. N. Cobbold and A. E. Underdown.—Practical applications of the piezoelectric behavior of crystals and their use for frequency stabilization are reported by the authors. Shapes and dimensions, modes of vibration, other frequency standards and a number of practical applications with particular reference to methods of frequency measurements are included. It is stated that in comparison with forks of special steel, quartz resonators possess the advantage that their natural frequencies are well within the limits of the frequencies used in wireless so that, in comparison with standard electrical circuits consisting of inductance associated with capacity, they are more compact and constant and of lower temperature coefficient. The method of mounting the crystals is indicated as being of considerable importance, as the dependence of the frequency upon the dimensions of the air gap and upon the presence of moisture has been clearly demonstrated. It seems probable according to this determination that the crystal should be mounted in a vacuum and that either blocks of fused quartz should be used as distance pieces between the electrodes, or else the air gap should be dispensed with altogether by pressing one of the electrodes on to the crystal by means of a light spring.—*Electrical Review (England)*, April 27, 1928.

*Tuned Radio-Frequency Amplifiers.*—R. S. Glasgow.—A simplified method of calculating the performance of a tuned amplifier circuit is given by the author and the effect of the various circuit constants on the characteristics is indicated. The predicted results are found to check quite closely with experimental observation. Curves showing the performance obtained with various types of tubes are also presented and the factors affecting the stability are pointed out and typical methods for suppressing undesired oscillations are given. The principles involved have been developed as a fundamental consideration applicable to such work.—*Journal of the American Institute of Electrical Engineers*, May, 1928.

### *Traction*

*Southern Railway Electrification.*—E. C. Cox.—The operating advantages and economies realized in the electrification of the Southern Railway (England) have been outlined by the author. Comparative cost data for railway operations are offered for several divisions of this road and for several other companies. — *Electrical Review (England)*, April 20, 1928.

### *Miscellaneous*

*The Strength of Flat Plates.*—Tandy A. Bryson, Thomas Cheeger and Harvard H. Gorrie.—The results of three investigations upon the strength and properties of square flat steel plates subjected to uniformly distributed pressure are offered by the authors. It is stated that the experimental conditions were such that the edges of the plates may be considered substantially as fixed edges. An equation to facilitate the design work in connection with flat plates was developed as a result of work by two investigators, working separately. Experiments to determine the strain actually produced in a flat plate under a uniformly distributed load, followed by an analysis of the stresses developed, is considered in the third paper. Among the conclusions derived are the following: The greatest stress does not occur in the center of the plate, as might ordinarily be expected, and ideal clamping conditions are necessary in order to check by practical investigation the theoretical conditions suggested by the equation.—*Rensselaer Polytechnic Institute*, April, 1928.

*A Thermodynamic Study of Fundamental Corrosion Reactions.* — W. J. Sweeney.—The fundamental corrosion reactions of iron in the absence of oxygen and the iron-ferrous ion-hydrogen equilibrium are discussed from an electromotive and free energy standpoint. From a critical survey of the literature on the solubility of iron and of ferrous hydroxide, a solubility product and a provisional value for the free energy of formation from the elements of ferrous hydroxide are obtained. With this value at hand the conclusion is drawn that there is a small free energy decrease for the attack of iron by water to form ferrous hydroxide and hydrogen even in the absence of oxygen. The interdependence of the iron, ferrous ion, hydrogen ion, hydrogen equilibrium and the ferrous hydroxide equilibrium is also pointed out.—*Report American Electrochemical Society*, April, 1928.

# Book Reviews

## *Transmission Line Engineering*

By W. W. Lewis. New York: McGraw-Hill Book Company. 360 pages, illustrated. Price, $4.

This is not a stereotyped book on electric power transmission. It is written by an experienced transmission engineer of a large manufacturing company and presents his solutions to the engineering problems most frequently encountered in practice.

The book will enable the student or engineer to calculate all the necessary constants of a line, to determine the performance of a line and to fix stability and power limits on a line. Other topics are the calculation of short-circuit currents, the control of triple harmonics, proper use of auto-transformers, control and calculation of line disturbances, calculation of line losses, telephone interference and line regulation.

College teachers will find this book splendid for use in their classes because of its thoroughness and scope. It is up to date and deals with problems of current importance. These problems should be presented to students, for they require fundamental electrical knowledge for their solution. Mr. Lewis restricts his treatment to electrical problems and rightly eliminates mechanical design features. His book is a welcome contribution to transmission literature.

## *Emile Berliner, Maker of the Microphone*

By F. W. Wile. Indianapolis: Bobbs-Merrill Company. 354 pages, illustrated. Price, $4.

A young man from Hanover started his American career as a clerk in a store and ended it as an outstanding contributor to the development of the telephone and talking machine. Inventive faculties of unusual order are found in Emile Berliner, and in the face of serious difficulties he brought his inventions to fruition and gained international recognition.

In this book the career of Mr. Berliner is outlined in a sympathetic and enthusiastic vein. In addition to an account of the personality and history of the inventor, it provides a résumé of the business and patent aspects of developments in the microphone, gramophone and radio. The early days of these arts called forth strenuous rivalries for success and an enormous amount of patent litigation. The original conception of Bell required a great amount of practical improvement to produce the telephone of later days, and Mr. Berliner did a great deal to develop the variable-contact transmitter, which forms an essential part of the modern telephone instrument. In those days technical knowledge was meager and yet practical, and empirical researches brought forth marvels in the electrical art. Bell, Edison, Berliner and Tesla are typical of noted inventors whose work became extremely valuable because they had the imagination to conceive inventions and in addition the untiring industry necessary to invention based on cut-and-try methods. Mr. Berliner has an enduring place as an inventor of the telephone transmitter, the lateral-disk gramophone record and the microphone. His life as outlined in this book should afford a stimulus to the youth of today.

## *Induction Motor Practice*

By A. M. Dudley. New York: McGraw-Hill Book Company. 236 pages, illustrated. Price, $2.50.

This book is a practical treatment of modern induction motors. It is well illustrated with halftones of machines and line drawings which show motor characteristics, winding schemes, control circuits and design details. Topics covered in chapters are: Fundamental considerations, rotating magnetic fields, mechanical parts and their assembly, windings, types of motors, electrical and operating characteristics, speed-torque curves, control, mechanical considerations and the circle diagram.

In the last part of the book a large number of practical questions about induction motors are asked and answered and a very good chapter is given on the circle diagram and its use.

The book does not develop a rigid mathematical and analytical treatment of the induction motor. It deals with results and applications, but should appeal to a large group of students, electricians and those using induction motors in industry.

## *American Universities and Colleges*

By David Allan Robertson. (The American Council on Education). New York and London: Charles Scribner's Sons. Cloth, 6 x 9 in., 884 pages. Price, $2.50.

The character, scope and organization of higher education in the United States is reviewed in Part I of this volume. Part II presents condensed information regarding each of the universities and colleges on the accredited list of the American Council of Education. Supplementary information regarding thirteen classes of professional and fifteen classes of graduate schools is given in Part I. For some unexplained reason, engineering schools have far less space in proportion to their number than the other schools. Thus 130 engineering schools are given less than three pages, while 25 schools of economics are given eleven pages.

It is a great pity that after bringing together so many figures on a variety of subjects as this volume contains, practically no summaries are included. Another sad lack of the volume is an introduction in the nature of a general summary. Valuable as the book is as a compilation, it is chiefly that and nothing more. Certainly a book sponsored by educators should supply digests of the data it contains instead of compelling thousands of users to make the digests separately or do without.

# Book Note

National Electrical Safety Code, fourth edition. By Department of Commerce. Washington, D. C.: U. S. Government Printing Office. 525 pages, illustrated. Price, $1.

The entire code, as revised, has been approved by the American Engineering Standards Committee as an American standard.

This edition represents only minor changes in the general substance of the rules. The regulations dealing with line construction probably incorporate more important changes than any of the other parts, since it is this field of construction regarding which the views of operating engineers represent the greatest diversity of opinion. The rules of this part and also of Part IV have been entirely rearranged, with the hope of facilitating reference and clarifying requirements. Part V, dealing with radio installations, is entirely new in substance and has been prepared to guide the installations of both antennas and interior equipment.

The code rules specifically provide for variation from requirements when circumstances warrant different practice. The rules have been made to recognize conditions as to climate and density of population where these involve a difference in the hazard or the number of persons exposed to the hazard.

The Blue Book (Electrical Trades Directory and Handbook), 1928. By Electrician. London: Ernest Benn, Ltd. 1,430 pages, illustrated. Price, 25 shillings net.

The book has been extensively revised. The greater part of the Legal Digest has been omitted and is replaced by a new and important feature, the Geographical Section, listing industry and allied trades in Great Britain, Scotland and Wales. Another feature is the more extensive use of celluloid thumb-index tabs. The various classifications of material and equipment listed are indicated by blue tabs. Red tabs are used to indicate Contents, Who's Who and Geographical Sections.

# Books Received

*Isolierte Leitungen und Kabel.* By Dr. Richard Apt. Berlin: Julius Springer. 235 pages, illustrated. Price, 13 marks.

*Hilfsbuch für die Elektrotechnik.* By Dr. Karl Strecker. Berlin: Julius Springer. 1,137 pages, illustrated. Price, 42 marks.

*Archiv für Elektrotechnik.* By Dr. Ing. W. Rogowski. Berlin: Julius Springer. 526 pages, illustrated.

*Vestiges of Pre-Metric Weights and Measures Persisting in Metric System in Europe,* 1926-1927. By Arthur E. Kennelly. New York: MacMillan Company. 189 pages. Price, $2.50.

*Berechnung von Drehstrom-Kraftubertragungen.* By O. Burger. Berlin: Julius Springer. 115 pages, illustrated. Price 7½ marks.

# News of the Industry

## Massachusetts for a Wide Rate Investigation

*Regulative Procedure Recently Discussed by Legislature Will Await Results of Sweeping Inquiry by Department of Public Utilities*

GOVERNOR FULLER of Massachusetts has signed a resolve providing for an investigation by the Department of Public Utilities of "ways and means for regulating in such manner as will be fair alike to the public and to gas and electric companies their rates, valuations and capital issues." In this connection the department will consider contractual relations between the companies and the state as recommended both by the commission and the Governor in their recent annual messages. The adoption of this resolve postpones action upon the regulative procedure lately under vigorous discussion in the Legislature of Massachusetts until next year.

## Special "Home Rule" Session of Illinois Legislature

On the advice of Mayor Thompson of Chicago, Governor Small of Illinois has called a special session of the Illinois Legislature, which convened at Springfield on Wednesday, May 15. Two bills in the interest of "home rule" for Chicago are the only business to be considered. While the traction situation in that city provides the reason for the special session, one of the bills is in the form of an amendment to the Illinois Commerce Commission act by which a local commission with all the powers now held by the state body might be set up and a clause which now permits appeals to be made from a local commission to the state commission would be eliminated. This bill, if passed, will obviously affect all Chicago utilities. The local commission would, by the terms of the bill, be elected, or jurisdiction over utilities might be vested in existing city officials.

## New Worcester Rate Survives Legal Technicalities

The 6-cent rate which the Worcester Electric Light Company had adopted, as reported in the ELECTRICAL WORLD for April 21, with the permission of the United States District Court, has been withdrawn from the tariffs on file at the State House, Boston, at the instance of the Massachusetts Department of Public Utilities, but is still in force in billing customers for service. The federal court had previously enjoined the commission from enforcing the maximum rate of 5 cents per kilowatt-hour ordered by the board last summer. The commission received a notification from the company some weeks ago that it proposed to establish a 6-cent rate in place of the former 7 cents beginning April 1. On that date bills began to be rendered on the 6-cent basis, and, according to a statement by President Robert W. Rollins to a representative of the ELECTRICAL WORLD, the company will continue to maintain the 6-cent rate unless it loses its fight in the courts against a lower tariff.

The Massachusetts commission, after deliberation, declined to sanction the compromise rate of 6 cents, evidently fearing that such action might from its point of view have an adverse effect upon the outcome of the case. Hearings are now progressing daily at Boston before Henry E. Warner, master, the company's side being first presented. The fundamental issue in the case is the method of ascertaining the rate base on which tariffs shall be made.

## Morin Muscle Shoals Bill Passes House

### Provision for Prepared-Fertilizer Manufacture Stricken Out—Boulder Dam Measure to Have Eight Hours' Time—Swing Assails Power Companies

BY A VOTE of 251 to 165, the House of Representatives on May 16 passed the Morin Muscle Shoals bill shorn of the clause providing for the government manufacture of fertilizer, in the place of which a provision for the manufacture of nitrogen alone was substituted. The Morin bill authorizes the government to operate its plants at Muscle Shoals and to sell both nitrogen and surplus power. The fertilizer clause succumbed to the avalanche of open attack upon it let loose by the National Fertilizer Association, which paid for full-page advertisements in Washington papers and brought scores of its members to the capital to work against the bill. The measure, which is similar to the Norris bill that passed the Senate, now goes to conference. Senator Norris indicated that no serious trouble is expected in reaching an agreement between the two houses.

The Snell substitute bill was defeated by a vote of 151 to 119. The Snell bill limited fertilizer manufacturing at Muscle Shoals to experimental work for a period of five years. An amendment offered by Representative Hoch of Kansas and aimed at the power section of the bill was passed by the House. It provides that the resale of power shall be regulated by the Federal Power Commission. Representative Quin of Mississippi, however, expressed the opinion that this amendment would be valueless because it constitutes a violation of state's rights. Other amendments adopted affecting this section include one introduced by Representative La Guardia of New York which grants preference to municipalities in the leasing of power and a committee amendment which insures that power shall not be leased in excess of the maximum amount needed for nitrogen fixation. Over the protest of Representative Byrne of Tennessee an appropriation of $2,000,000 was authorized to begin construction work on the Cove Creek dam during the next fiscal year. Provision for all dams below Cove Creek was stricken out of the bill.

For the Boulder Dam bill a rule has been granted allowing eight hours' time for its consideration on the floor of the House. The bill probably will come before the House next Tuesday. Representative Swing of California, coauthor of the bill, has issued a statement protesting against activities of senators from Arizona and Utah in seeking to postpone consideration of the bill. Mr. Swing also took occasion to censor the power companies for their opposition to his bill. He declares, however, that "their fight will be less effective since the Federal Trade Commission exposure of their disguised activities and insidious use of 'undercover' methods in newspapers, colleges and chambers of commerce."

The President has signed the flood-control bill and appointed Carleton W. Sturtevant of New York as civil engineer member of the commission created.

## Arkansas Utilities Association at Hot Springs

Members of the Arkansas Utilities Association, 250 strong, convened at Hot Springs, Ark., on May 14, 15 and 16 for the twenty-first annual convention of that body. The program dealt largely with the problems of light and power companies and with public relations. Among the prominent speakers were former Governor C. H. Brough, J. F. Owens of Oklahoma City, chairman of the Public Relations National Section of the N.E.L.A.; C. J. Griffith, vice-president Arkansas Power & Light

Company; Earl W. Hodges of Henry L. Doherty & Company; D. Dodson Lewis, secretary-manager Little Rock Chamber of Commerce, and F. Leslie Body, secretary-manager Hot Springs Chamber of Commerce. The retiring president, Robert M. Foster, Jr., vice-president Arkansas Utilities Company, Helena, made an official address. The election of new officers was to take place on Wednesday.

## Trade Commission to Send Another Questionnaire

*Information on Holding, Management and Service Companies Sought—More Information Bureau Men Heard—Municipal Propaganda Ignored*

AN ADDITIONAL questionnaire is to be sent out by the Federal Trade Commission in connection with its utilities investigation. The additional schedules have been prepared and are now being studied by the commission. They call for comprehensive information upon (1) the growth of capital assets and capital liabilities of holding-company and management groups, including their public utility and non-public utility subsidiaries, and of independent operating companies doing an interstate business; (2) the methods of issuing, the price realized and the commissions, bonuses and fees received or paid by such companies with respect to the various issues of securities made by them; (3) the intercompany relationships among holding companies, managing or service companies and financial, engineering, construction and electric and gas operating companies, and (4) the services furnished to electric and gas public utility companies by holding, management and service companies, the expenses and earnings of such companies, together with the fees, commissions or bonuses charged by them or their subsidiary or affiliated companies.

Provision is also made in these schedules to obtain information concerning political campaign contributions and the expenditure of funds to be used to influence or control public opinion with respect to municipal or public ownership of electrical power enterprises. Representatives of the commission are now visiting the offices of certain large holding and service companies in New York City, Philadelphia and Chicago, acquiring data on the various phases of the inquiry from the official records of the companies. As soon as available other examiners will be sent to other power-company groups.

Examination of R. J. Holly of Sanford, Fla., director of the Florida Public Utilities Information Bureau; H. E. Simpson of Miami, treasurer of that bureau and also of the Southeastern Division, N.E.L.A., and Willard Cope, executive secretary of the Utilities Information Committee of Georgia, took up the May 10 sessions of the investigation of utilities. Nothing of a nature to attract public attention or special political attack was developed by the testimony of the Florida men. Mr. Cope told of his committee's fight in 1921 against water-power legislation sponsored by the Municipal League of Georgia. The bureau had spent an average of $30,000 a year, he testified, but all vouchers and financial records were destroyed at the end of each year as a matter of office routine. The discontinuance of the legislative agitation over water power in Georgia Mr. Cope attributed to the death in 1924 of John J. Eagan of Atlanta, its chief advocate. He testified regarding the circulation of a weekly news bulletin, *The Week*, and discussed the distribution of various pamphlets relating to public utilities.

When the commission resumed its sittings on May 15, Joe Carmichael, director of the Iowa Committee on Public Utility Information, was questioned about the efforts of that committee to influence instruction in the public schools concerning public utilities. This is a line of inquiry that the commission has consistently followed. Mr. Carmichael said that schoolbooks were removed by local school authorities when protest was made that they contained matter favorable to government ownership of power units. The protests were voiced by local managers of utility companies.

On Wednesday Thorne Browne, managing director Middle West Division, N.E.L.A., was examined regarding the distribution of textbooks and pamphlets to the schools of Nebraska and Missouri. Mr. Browne said that the object was to provide supplemental information not covered by school textbooks and to achieve "better understanding on the part of the rising generation of the scope and field of public utilities." He said he could see no impropriety in the use of impartial material in such a way. The fact that the supplier of this material may have had an interest to serve would make no difference if the material itself were right.

Officials of telephone and telegraph companies were then called in an effort to obtain a check on messages to and from the Washington offices of the Joint Committee of National Utility Associations. S. E. Boney of the North and South Carolina Public Utilities Information Bureau was summoned to give testimony on Thursday morning.

In denying a request made by Representative Douglas of Phoenix, Ariz., that the investigation include the "lobby" working in behalf of the Swing-Johnson bill for the development of Boulder Dam, Judge McCulloch, the member of the Federal Trade Commission in charge of the investigation, stated that the full commission "adheres to its conclusion that the province of this investigation is directed entirely to privately owned utilities and not to those municipally owned." "We are not concerned here with the merits of Boulder Dam, nor with any city or public project, but we are only concerned with the activities of privately owned utilities," Judge McCulloch said.

There will be no hearings next week, as Judge McCulloch will be absent from Washington.

## Renewal of Demand for Curb on Federal Courts

*Samuel Untermyer Wants Limitation of Their Jurisdiction in Rate Cases, Basing His Argument on Traction Situation in New York*

PERMISSION granted by the United States District Court to the Interborough Rapid Transit Company of New York City to raise its fare from 5 cents to 7 cents has augmented the agitation for passage by Congress of a law limiting the jurisdiction of the federal courts in rate cases. Samuel Untermyer, special counsel for the city, last Saturday supplemented a memorial to Congress from the city's Board of Estimate by requesting Senators Copeland and Wagner, who represent New York State in the Upper House, to get behind legislation to this end.

Representative Loring M. Black of Brooklyn has a bill pending before the House judiciary committee which would amend the federal code by taking original jurisdiction in rate cases away from the federal courts. Under this bill, as under bills introduced by Representatives O'Connor and LaGuardia, the public utility companies would be required to bring their proceedings in the state courts. A bill including similar provisions has been fathered by Senator Norris in the other house. Utility companies would, of course, still have an appeal to the United States Supreme Court from the highest state courts.

## Ten-Thousand-Dollar Arc-Welding Prize Awarded

Award of $17,500 in prizes for the best contributions to the arc-welding art was the outstanding event at the opening session of the spring meeting of the American Society of Mechanical Engineers at Pittsburgh on Monday of this week. These prizes were offered by the Lincoln Electric Company of Cleveland through its vice-president, James F. Lincoln, with the desire to promote the whole art and to reduce the cost of construction.

The first prize, $10,000, was awarded to James W. Owens of Newport News, Va., for a paper entitled "Arc Welding. Its Fundamentals and Economics." Prof. Henri Dustin of the University of Brussels, Belgium, received the second prize of $5,000 for his paper on "Fundamental Principles of Arc Welding," while Commander H. E. Rossell of the United States Naval Academy took the third prize of $2,500 for his review of "Electric Welding of Ship's Bulkheads and Similar Structures."

Seventy-seven papers were entered in the contest from twenty-five states and five foreign countries. Honorable mention was given to Frank B. Walker of Winthrop, Mass., and B. K. Smith of Houston, Tex.

There was a central-station power session of the society on Thursday, with papers by H. B. Brydon and George A. Orrok.

# Ten Thousand Expected in Atlantic City

## Many Prominent Men and Women from Outside the Industry Will Unite with Its Own Leaders to Address Delegates on Vital Present-Day Topics

SAVE for the names of two speakers to be added to those addressing the general sessions and for the exact titles of several others of the addresses promised, the program of the fifty-first convention of the National Electric Light Association, to be held at Atlantic City on June 4 to June 8 inclusive, is ready. The functions of holding and investment companies, interconnection, railroad electrification, rural service, research, advertising, merchandising problems and the commercial outlook will be especially prominent in the addresses and discussions, as will the absorbing present-day topic of "government and business." An imposing array of speakers will address themselves to these subjects, and a thoroughly successful convention is foreseen. The estimated attendance of delegates and visitors is ten thousand, representing every part of North America.

Speakers from outside the light and power industry will include Melvin A. Traylor, president of the First National Bank of Chicago, who will make the chief address on "public policy night"; Dan Moody, Texas' famous young governor, who will be the main speaker from the sphere of politics; Samuel M. Vauclain, president of the Baldwin Locomotive Works; J. E. Edgerton, president of the National Association of Manufacturers; H. P. Davis, chairman of the National Broadcasting Company's board; Lawrence A. Downs, president of the Illinois Central Railroad; Hugh Frayne, representing the American Federation of Labor; H. G. Wells, president of the National Association of Railroad and Utilities Commissioners; Deane W. Malott, assistant dean of the Harvard Graduate School of Business Administration; P. W. Pinkerton, president of the American Society of Certified Public Accountants; Clifford V. Gregory, editor of the *Prairie Farmer;* Miss Belle Sherwin, president National League of Women Voters; C. O. Ruggles, dean of the College of Commerce and Administration, Ohio State University; William P. MacCracken, Assistant Secretary of Commerce; Merle Thorpe, editor *Nation's Business;* John T. Madden, dean School of Commerce, Accounts and Finance, New York University; Mrs. John D. Sherman, president General Federation of Women's Clubs; David Himmelblau, School of Commerce, Northwestern University; S. N. Halliday, General Outdoor Advertising Company; Mrs. Anna S. Richardson, *Woman's Home Companion,* and Clayton Rand, president Dixie Press, Gulfport, Miss.

From the industry itself, to speak at the general or the sectional sessions, are listed President H. T. Sands, Managing Director Paul S. Clapp and Director of Engineering H. S. Bennion of headquarters; Chairmen J. E. Davidson, E. A. Davis, E. C. Stone and J. F. Owens of the Commercial, Accounting, Engineering and Public Relations National Sections respectively; A. W. Thompson, president United Gas Improvement Company; Britton I. Budd, president Public Service Company of Northern Illinois; Franklin T. Griffith, president Portland Electric Power Company; Dr. W. R. Whitney, director of research, General Electric Company; W. W. Freeman, president Society for Electrical Development; John F. Gilchrist, vice-president Commonwealth Edison Company; James H. McGraw, president McGraw-Hill Publishing Company; George N. Tidd, president American Gas & Electric Company; Herbert A. Wagner, president Consolidated Gas, Electric Light & Power Company; W. E. Mitchell, vice-president Georgia Power Company; Charles B. Scott, Earle W. Hodges, E. W. Lloyd and A. D. Bailey.

The usual ample reports will be presented by the well-known men who head the general and sectional committees, and the Coffin, Forbes and other prize awards will be made.

The exhibition is expected to surpass all previous ones, every foot of space on the Million-Dollar Pier not occupied by assembly halls, offices and special booths (including one for good-will and institutional advertising material) having been assigned to the 206 manufacturers who will make displays. B. A. Rolfe's orchestra has been engaged to provide music in aid of the excellent entertainment program under preparation. It will also play at the public policy eve-

## N.E.L.A. Convention Program, Atlantic City, June 4-8

### General Sessions

TUESDAY, JUNE 5, 9:30 A.M.

Address of welcome, Mayor Ruffu.
Address by President H. T. Sands.
Reports of treasurer, membership committee, managing director and of Public Relations Section.
"Why the Investment Company," A. W. Thompson.
"Broadcasting," H. P. Davis.

WEDNESDAY, JUNE 6, 9:30 A.M.

Reports of exhibition, codes and standards, and rate research committees and of Commercial Section.
"The Electric Utility and the Public," Henry G. Wells.
"Government and Business," John E. Edgerton.
"Universities and Industry," Dean D. W. Malott.
"Speeding up for Prosperity," S. M. Vauclain.

WEDNESDAY, JUNE 6, 2:30 P.M.

*Forbes Magazine* awards.
Symposium, "Railroad Electrification," B. I. Budd and L. A. Downs.
"The Accountant as a Torch Bearer to Management," P. W. Pinkerton.
Report of rural service committee.
"Electricity and the Farmer," C. V. Gregory.
"Power in Political Education," Belle Sherwin.

THURSDAY, JUNE 7, 9:30 A.M.

Reports of prize awards and lamp committees and of Accounting Section.
"The Clearing House of the Industry," F. T. Griffith.
"Education of Men for the Public Utility Industry," Dean C. O. Ruggles.
Address by Governor Moody of Texas.
"Electrical Research and Progress," Dr. W. R. Whitney.

THURSDAY, JUNE 7, 2:30 P.M.

Reports of educational committee and of Engineering Section.
"Teamwork for Electrical Development," W. W. Freeman.
"Commercial Aviation," W. P. MacCracken.
Address by Hugh Frayne.
"From Bottom up or Top Down," Merle Thorpe.
"The Investment Company in Business Development," J. T. Madden.

FRIDAY, JUNE 8, 9:30 A.M.

Reports of memorials, insurance and other committees.
Address by Mrs. J. D. Sherman.
"Electrical Advertising," J. F. Gilchrist.
Address by James H. McGraw.
"Interconnection with Its Benefits," George N. Tidd.
Appreciation, H. A. Wagner.
Election of officers.

### Public Policy Committee

WEDNESDAY, JUNE 6, 8:30 P.M.

Presentation of Charles A. Coffin Award.
Report of public policy committee.
Address, Melvin A. Traylor.
Music and dancing

### Accounting Section

TUESDAY, JUNE 5, 2:30 P.M.

Address by Chairman E. A. Davis.
"Insurance Costs," Charles B. Scott.
"Common Sense and Dollars," E. W. Hodges.
"Accounting Treatment of Securities Discount and Expense," D. Himmelblau.
"Some Problems for the Accountant," E. W. Lloyd.
Reports of committees.

### Commercial Section

TUESDAY, JUNE 5, 2:15 P.M.

Address by Chairman J. E. Davidson.
Address by Samuel N. Halliday.
Reports of committees.

### Engineering Section

TUESDAY, JUNE 5, 2:30 P.M.

Address by Chairman E. C. Stone.
"Purposes and Accomplishments of Engineering Staff," H. S. Bennion.
"Organizing the Industry's Engineering Research," A. D. Bailey.
"Spending Our Company's Money," W. E. Mitchell.
"Engineering for the Future," E. C. Stone.

### Public Relations Section

TUESDAY, JUNE 5, 2:30 P.M.

Address by Chairman J. F. Owens.
"Woman's Place Is in the Home," Mrs. A. S. Richardson.
"Thunder and Lightning," Clayton Rand.
Reports of committees.

ning meeting, when there will be other music as well.

An open meeting for women delegates, with two sessions, will be held at the Dennis Hotel on Monday morning and afternoon, under the guidance of Miss Sophia Malicki. The session of the Commercial National Section will be held in the Haddon Hall Hotel and that of the Accounting National Section in the Hotel Traymore. All other sessions will be on the Million-Dollar Pier.

---

# "Electrical World's" London Letter

## Central England Electricity Scheme Announced—British Industries Fair and Electrical Trade—"House of the Future"—Cable-Wireless Merger

By Bernard C. Holding

*Editor of The Electrician*

London, April 28, 1928.

Outstanding in importance among electrical items of early spring was the publishing of the proposed electricity scheme for operation under the Central Electricity Board for the central England area. This constitutes the third scheme so far published, the other two covering Scotland and southeast England. The proposed arrangements for central England embrace an area of approximately 7,000 square miles, including virtually the whole of the industrial zones of the Midlands, and they comprise the whole or the major portion of the areas of supply of 49 existing authorized electricity supply undertakers. The sale of electricity in the area in 1926-27 by all the undertakers concerned was 762,000,000 kw.-hr., equal to about 146 kw.-hr. per head of population according to the 1921 census. A rate of growth has been taken as the basis of estimates for the scheme, which would give a sale in 1934-5 of 1,890,000,000 kw.-hr., or 362 kw.-hr. per head. It is expected that by 1940 the output will have reached 2,820,000,000 kw.-hr., or 540 per head. Of the 46 generating stations at present operating in the area, it is proposed that 19 be taken as "selected" stations, while six others will be used as temporary stations. The remaining 21 stations will be gradually closed down as generating stations and made into transformer stations. The total expenditure in the Midlands scheme may be given as about £7,500,000 during the first six years, while the saving to the authorized undertakers is put down as about £1,500,000.

Another interesting feature of last month was the closing of the British Industries Fair, at Birmingham and London, for another twelve months. The electrical section of the fair was again very successful, no single instance having been heard in which the fair was thought to be not worth while; in fact, the immediate success of the exhibition as a promoter of trade has been greater than some exhibitors anticipated.

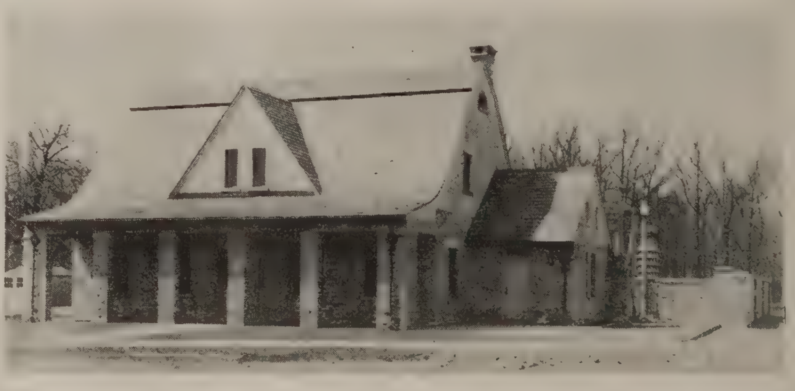
Still another successful exhibition during March, in which the electrical industry played a not inconsiderable part, was the "ideal home exhibition" held in London. Here was shown an example of the house of the future. Lighting, heating, cooking, cleaning and services of every description were all electrical, and from the time one entered the garden it was practically impossible to find anything which was not in some way associated with electricity.

With regard to the announcement during March of the fusion provisionally arranged between the Eastern & Associated Telegraph Companies and Marconi's Wireless Telegraph Company, this does not necessarily mean that the problems of either party are entirely solved. It is not in any way certain at present that a satisfactory agreement with the British government and the governments of the Dominions and Canada can be arrived at, although no suitable alternative seems possible. Government control of telegraphic communication has not, on the whole, proved profitable; the general feeling is therefore that the Post Office may not be anxious to hand over those enterprises, including the "beam" service, which are understood to be making a profit. Be this as it may, the final decision must rest with the Imperial Wireless and Cables Conference, which is thus confronted with as heavy a responsibility as any commission in recent years has had to bear. The world has eagerly paid tribute to the genius of Marconi and the wonders that have evolved through his organization. Justice, however, suggests recognition of the fact that the Marconi enterprise is scarcely 30 years old, while the cable has been facilitating and expediting the progress of the world for about 80 years. When, in 1851, Brett laid his Dover-Calais cable, after a fierce struggle to secure the £300 necessary for the experiment, it may be said, however, that he scarcely anticipated the amazing expansion of cabling, with its record of brilliant achievements.

On the personal side it is interesting to note that Sir Oliver Lodge, F.R.S., was admitted a freeman of the city of Stoke-on-Trent, his birthplace, while Sir Alexander Kennedy, F.R.S., celebrated his eighty-first birthday on March 17. George Offor, an electrical pioneer, celebrated his one hundred and first birthday on March 30, and on the same day a jubilee dinner was given to Col. R. E. Crompton to commemorate the founding of Cromptons, Ltd., 50 years ago. J. M. Gatti was elected chairman of the British Electrical Development Association, and it was announced that Dr. J. A. Fleming, F.R.S., is to be awarded the honorary degree of doctor of engineering by Liverpool University in May. Among those this month whose loss will be widely felt are Sir William B. Forwood, one of the founders of the Liverpool Overhead Railway Company, and John P. Hooper, who superintended the manufacture of cables which were laid between Para, Pernambuco, Bahia and Rio de Janeiro from 1872 to 1875.

---

# Unique Substation in Residential Part of South Bend



The unusual type of substation building shown here was erected not long ago by the Indiana & Michigan Electric Company to serve South Bend from the company's 27,000-volt loop around the city. Building restrictions made it obligatory to design a building that would largely conceal the electrical apparatus and enhance rather than depreciate the value of the adjacent lots. The building is 30 ft. wide by 40 ft. long, built of brick with a slate roof of varied colors. The windows and doors are equipped with shades and curtains similar to those of any fine residence. From the street it has the appearance of a bungalow. There is 200 ft. of underground construction connecting it with the overhead loop. The station contains four 1,000-kva., 27,000/2,500-volt single-phase transformers, three for service and one as a spare. The 27,000-volt apparatus is out of doors back of the substation building and surrounded by a brick wall such as might surround a garden.

## Purchases and Mergers

*Plans Mature for the Acquisition of the Brooklyn Edison Company by Consolidated Gas—Merger of Penn-Ohio Edison and Northern Ohio Power Becomes Effective*

OUTSTANDING this week in news involving changes in the control of light and power companies is the approval by both the trustees of the Consolidated Gas Company of New York (which controls the New York Edison and its associated companies) and the directors of the Brooklyn Edison Company of the plan mooted for some time for the acquisition of the latter by the former, thus bringing all the Brady electrical interests in Greater New York under a common management. When this plan shall have been indorsed by the stockholders of the respective companies, the only electric light and power companies of size in the metropolitan area not included in the consolidated group, whose capitalization will exceed $1,343,000,000, will be the Long Island Lighting Company and the Staten Island Edison Corporation. Details of the proposed financial arrangement are printed under "Financial and Statistical" (page 1039).

The merger of the Penn-Ohio Edison Company and the Northern Ohio Power Company, noted in the Electrical World for April 21 (page 829) as under negotiation, was declared effective on May 15.

No opposition was made on May 9 before the New York Public Service Commission to the petition of the New York Power & Light Corporation to acquire the Ticonderoga Electric Light & Power Company or to the petition of the Mohawk-Hudson Power Corporation to acquire the Cortland County Traction Company, which does a light and power business. The decision of the commission was reserved.

Purchase of the Ardmore Light & Improvement Company by the Annapolis & Chesapeake Bay Power Company, a subsidiary of the Consolidated Gas, Electric Light & Power Company of Baltimore, has been approved by the Maryland Public Service Commission.

A petition asking authority to purchase electric transmission lines and property in seven Indiana counties, including Marion County, has been filed with the Indiana Public Service Commission by the Southeastern Indiana Power Company of Indianapolis. The lines in question belong to the Evans Electric Company, the Eastern Light & Power Company and the Suburban Power & Light Company. The petitioning company asks to be declared a public utility.

The Interstate Public Service Company of Indianapolis has been authorized by the Indiana Public Service Commission to pay $35,000 for the properties of Frank Crull, known as the Home Light & Power Company, at Mooreland, Millville, New Lisbon, Ashland and Messick.

The North Dakota Railroad Commission has authorized the Otter Tail Power Company to purchase the Clyde Electric Company and the Page Electric Company. A recently printed report that the Otter Tail company had bought the Eckelson (N. D.) plant was erroneous. A proposal to sell the electric distribution system at Williston, N. D., to the Montana-Dakota Power Company was defeated at a special election by a margin of 299 votes. Williston has 4,000 people.

To the Great Western Power Company of California permission has been granted by the Railroad Commission to purchase all of the outstanding stock of the Fair Oaks Electric Company and to consolidate the property with its own system. The company, which has been purchasing its energy from the Great Western, serves a district 12 miles northeast of Sacramento. The Great Western was directed to charge to capital account not more than $28,736 of the purchase price, excess indebtedness of the Fair Oaks company to be charged to profit and loss.

Several utilities at Ketchikan, Alaska, have been purchased by the W. B. Foshay Company of Minneapolis, including the Citizens' Light, Power & Water Company, and are to be merged as soon as possible with other public utility holdings of the Foshay company.

Consummation of the arrangement by which financial interests represented by Nesbitt, Thomson & Company, the Power Corporation of Canada, Sir Herbert Holt, Lord Rothermere, the Canadian & Foreign Power Corporation, J. H. Gundy and Andrew Holt & Company are to take ownership of the British Columbia Electric Railway Company is announced.

## Chamber of Commerce Adopts Resolutions

### Denounces Unethical Practices and Corruption of Public Servants—Declares Against Government in Business and Against Limiting Power of Federal Courts

A RECORD-BREAKING attendance, the presence of scores of industrial leaders of the first rank from all parts of the country, the high character of the addresses, the willingness shown to exercise guidance in the ethical, economic and legislative problems that confront business, and the determination evinced to make American industry worthy of the pre-eminence it has achieved among the factors that control the social life and progress of the nation, combined to make the sessions of the Chamber of Commerce of the United States that closed at Washington on May 11 the most memorable yet held by that body. Before adjourning, the chamber, some of whose proceedings with a special bearing on the electric light and power industry were reported at length in last week's Electrical World, adopted seventeen resolutions.

*William Butterworth*

In one of these resolutions, based on the keynote address of Judge Edwin B. Parker, unethical practices in business were condemned and stockholders were told that they "cannot accept the profits flowing from corruption and escape the moral stigma which inheres in such profits." This resolution declared further that American business "insists upon protecting its professional status by the maintenance of the highest standards and intends scrupulously to discharge its collective responsibilities." "The moral turpitude of corrupters of public servants is even greater than that of those whom they debauch," the resolution said:

Another resolution dealt with "government and business," specifying "transportation and communication" as fields the government should not enter. This resolution reads:

> The very essence of civilization is that there be placed upon the individual only that degree of restraint which shall prevent his encroachment upon the rights of others, thus releasing to the utmost individual initiative in every proper direction. Our form of government most effectively expresses and maintains this principle. Within our basic law exists ample provision for such changes as may from time to time be necessary to safeguard our people. It is, therefore, essential that our government should scrupulously refrain from entering any of the fields of transportation, communication, industry and commerce, or any phase of business when it can be successfully undertaken and conducted in the public interest by private enterprise. Any tendency of government to enter such fields should be carefully weighed in the light of its possible effect upon the very genius of our institutions.

Other resolutions passed opposed limitation of the power of the federal courts and advocated a reduction in the corporation tax to 10 per cent, improvement of federal tax laws and administrative regulations, the application of the budget system to state and local expenditures, legislation for the encouragement of shipbuilding by responsible private interests, extension of the Webb-Pomerene act to include import associations, compilation of more comprehensive industrial statistics, enactment of the Hague rules for ocean bills of lading in so far as applicable to America, and international commercial arbitration.

The board of directors elected the following officers for the ensuing year: Chairman of the board, Joseph H. Defrees of Chicago; president, William Butterworth, Moline, Ill.; vice-president Eastern Division, Alfred J. Brosseau, New York; vice-president South Central Division, Robert R. Ellis, Memphis; vice-president North Central Division, Robert P. Lamont, Chicago; vice-president Western Division, Paul Shoup, San Francisco.

# Merger Movement Fundamentally Sound

## President of Middle West Division, N.E.L.A., Points Out How Individual Operating Companies Benefit from It—Public Relations and Commercial Development

UNSWERVING determination on the part of electric utility executives, operators and employees to stand for and demand complete vindication of their industry overshadowed all else at the sixth annual convention of the Middle West Division, N.E.L.A., held in St. Louis on May 9-11.

Utility men must realize that they are living in a day when all businesses are in a melting pot of mergers and consolidations, said Don M. Sterns, president of the division, at the opening session. Fundamentally and economically this movement is sound, and in the central-station industry, through holding-company operation, individual companies have benefited directly by being able to do cheaper financing, install better and more efficient equipment and in turn reduce rates to the public. This has been possible in spite of the fact that costs of labor and materials for producing electricity have increased in line with other commodities.

The importance of the electrical industry and electrical service to a metropolitan city was emphasized in the address of welcome by Mayor Victor J. Miller, who pointed out that of $87,000,000 to be spent in St. Louis on civic improvements in the next five years between $8,000,000 and $9,000,000 will be for electrical improvements.

J. F. Owens, chairman Public Relations National Section, outlined the functions and purpose of his various subcommittees and made a plea that utility executives get a fuller appreciation of value of service on association committees.

The condition of farmers is of direct concern to utilities and the principal problem of the Middle West, declared F. J. Hanlon, Mason City, Iowa. He pointed out that there are many parallel conditions when utilities and farming are considered as businesses. Both have high investments, a low rate of capital turnover and high taxes, with problems of quantity production.

Speaking on "Some Fundamentals Under Government," Carl D. Jackson, chairman of the national committee on co-operation with educational institutions, declared that the utilities have a constitutional right to organize and engage in publicity for self-preservation.

H. T. Sands, president of the national body, in his address on "The Full Measure of Service," said that the greatest danger is from the public utility man who believes his public relations work is all done. He is due for a rude awakening.

Louis H. Egan, president Union Electric Light & Power Company, reviewed the developments in public utility financing in the Middle West, pointing to the changed conditions as compared with the early years of the industry, when utilities were financed partly by promoters and partly by electrical manufacturers.

That the sale of more electric service to existing customers is one of the best means of building better public relations was emphasized by J. E. Davidson, chairman Commercial National Section, N.E.L.A., who addressed the meeting on "Commercial Developments in the Electrical Industry." Commercial activities in the Middle West were traced by W. J. Krug, chairman of the division's Commercial Section, who pointed out to commercial men that their plea of lack of executive interest in commercial activities may be due largely to the commercial man's own failure to present his story in complete and tangible form to his executive.

Public utilities are taking more and more active interest in rural electrification, C. F. Stuart, Northern States Power Company and chairman national rural electric service committee, asserted. Soon to be published by Mr. Stuart's committee will be a report on "Four Years' Operation of the Red Wing Line," which it is expected will provide an affirmative answer to the question whether electricity pays its way or not on the farm.

Discussing some phases of "Government in Business," Judge C. W. Appleton, vice-president General Electric Company, declared that the present form of state regulation of utilities is in the best interest of the public and the companies themselves and pointed out difficulties that would be encountered if some method of federal regulation were undertaken instead.

Training of utility employees to engage in public speaking as part of the utilities' public relations program was considered vitally important by W. S. Vivian, chairman N.E.L.A. public speaking committee. J. B. Sheridan, director of Missouri Committee on Public Utility Information, in an address on "Telling the Public," outlined the work of his committee.

"The Banker's Point of View" was the subject of an address by A. C. Allyn, president A. C. Allyn & Company, on Friday morning. Relations between utility operators and the banker have changed greatly in the last eight years, he said. From a combative attitude which formerly existed both the banker and the operator have come to realize that the interests of the utility owner, the operator, the banker and the investing public are the same. Mr. Allyn traced the decreasing cost of investment money for utilities over the last few years and prophesied that interest rates would probably go lower than they are today and that many companies will be able to put out bonds bearing 3½ per cent coupons.

"Superpower—What Is It?" was the subject of an address by E. S. Hight, chief engineer North American Light & Power Company, who described in detail the development of electric service in the Middle Western States. Other addresses on Friday morning were on "Flood Control," by Major George R. Young, and "The Poetry of Power," by the Rev. W. C. Timmons, St. Louis.

The annual banquet and carnival held on Thursday evening was attended by about four hundred members and guests. At the close of the meeting the following officers were elected for the ensuing year: President, R. T. Smalley of the Kansas Electric Power Company; vice-presidents, A. E. Bettis of the Kansas City Power & Light Company, K. R. MacKinnon of the Nebraska Power Company and E. F. Buhlman, of the Iowa Southern Utilities Company; managing director, Thorne Browne.

# Briefer News

UNITED LIGHT & POWER MOVES FROM GRAND RAPIDS.—The home office of the United Light & Power Company was moved early this month from Grand Rapids, Mich., to Chicago, whence all of the administrative and executive functions of the company will be directed. The new address is 2200 Bankers' Building.

CENTRAL MAINE POWER REDUCES RATES.—The Central Maine Power Company is proceeding with a general revision and standardization of rates throughout its territory. The latest change is a reduction affecting the southern division beginning June 1 and averaging 10 per cent. It will include customers in Bath, Brunswick, Lisbon and ten or twelve smaller places.

NEW IRRIGATION AND POWER DAM IN MEXICO.—President Calles of Mexico last week laid the first stone of the Tepuxtepec Dam, to be constructed in the State of Michoacan jointly by the Mexican Light & Power Company and the Mexican government. It will cost $10,000,000 and permit the generation of 30,000 hp. in addition to the irrigation features of the project.

ELECTRICAL AND ENGINEERING BUILDING FOR TORONTO EXHIBITION.—The first sod on the site for a new electrical and engineering building at the Canadian National Exhibition, Toronto, was turned by Mayor McBride on May 4 in the presence of a large gathering. The structure will cost upward of $500,000. All space has been already leased for a term of years.

NEW GENERATING PLANT FOR EVANSVILLE, IND.—A two-million-dollar steam-electric power plant is to be built in Evansville, Ind., by the Southern Indiana Gas & Electric Company. Work on the plant will start at once, and it is expected to be ready for operation by the fall of 1929. The plant will be built on the Ohio River in the part of Evansville known as the West Side on a site of 20 acres just purchased by the company. The new plant will be linked with the Division Street plant, which will be kept in operation and used as the main distribution station. The first unit to be installed will have a rating of approximately 22,500 kw., and an ultimate station capacity of five times as much is provided for.

Progress on New Municipal Plant at Hamilton, Ohio.—Electricity will be generated at the new municipal electric light plant of Hamilton, Ohio, in September or October, according to a forecast just made by F. H. Froehlich, the engineer who drew plans for the plant. The plant, complete, will cost $750,000, according to Mr. Froehlich's estimate.

East River Plant of New York Edison Company Inspected by Electrical Society.—Seven hundred members of the New York Electrical Society visited the new East River generating station of the New York Edison Company last Saturday and were escorted through the plant, speeches being made by Dr. E. E. Free, president of the society, and Vice-Presidents Thomas E. Murray, John W. Lieb and Arthur Williams of the company.

Intensive Development Planned for Tidewater Virginia.—The development in tidewater Virginia of six electrical divisions, with centers respectively at Waverly, West Point, Urbanna, Chicoteague, Onley and Colonial Beach, is planned by the Virginia East Coast Utilities Company, according to President W. F. Stevens. Surrounding communities will be linked to these central points and considerable territory hitherto without service will be supplied.

Calgary Power Company Gets Bow River Site.—The Calgary Power Company of Calgary, Alberta, has obtained a lease of the water-power site on the Bow River at its junction with the Ghost River (Electrical World, May 5, page 934), an announcement from Ottawa says. Application for this site was in the nature of an alternative to the development of Spray Lakes power, which is left in abeyance. It is asserted that the additional power to be had from the Bow River will take care of the requirements of the Calgary Power Company during the next five years.

Commission Gives Public Service Company of Colorado a Month to File Royal Gorge Brief.—After hearing testimony from municipal officials of Cañon City, Colo., in favor of the application of the Public Service Company of Colorado for permission to erect a power plant in the Royal Gorge, the Public Service Commission of the state gave the company thirty days in which to file a brief. This time will expire two weeks hence, after which final argument will be heard and the decision rendered. Engineers, ranchmen, farmers and fruit growers, who fear interference with water supply, as well as those who fear injury to the scenic attractiveness of the gorge, have opposed the application.

Hydro Plant Contemplated in Kentucky to Serve Mines and Power Companies.—A permit for which L. E. Bryant of Roberta, Tenn., has applied to the Federal Power Commission would allow him to construct two power dams on the Rock Castle and Laurel Rivers in Kentucky. The power would be used in coal operations and the surplus sold to power companies in the vicinity. The estimated installed capacity contemplated is 39,300 hp. The two dams would store 20,000,000,000 cu.ft. of water.

Conditions Good in Southeast for Hydro Generation. — Water supply and stream conditions as they affect hydro-electric power in the Southeastern States are the best in years, according to reports made by representatives of the power concerns in the territory who met last week at Raleigh, N. C. The meeting was that of a committee on operations, composed of officials of the larger power companies in Virginia, West Virginia, North and South Carolina, Georgia, Alabama and Tennessee. It was brought out that reservoirs are in better shape and stream flow better than at any time in recent years at this season of the year. With normal rains throughout the summer no shortage of power is expected and it will probably not be necessary to plan extensive interchange of energy.

## *Coming Meetings*

[A complete directory of electrical associations, with their secretaries, is published in the first issue of every volume. For latest list see Electrical World for Jan. 7, page 80.]

Indiana Electric Light Association (jointly with Indiana Public Utilities Association) — Columbia Club, Indianapolis, May 22-24. William Stokes, 1548 Consolidated Bldg., Indianapolis.

National Electric Light Association—Atlantic City, June 4-8. P. S. Clapp, 420 Lexington Ave., New York.

American Association of Engineers—Hotel Hussman, El Paso, Tex., June 4-6. M. E. McIver, 63 E. Adams St., Chicago.

Electrical Supply Jobbers' Association—The Homestead, Hot Springs, Va., June 5-8. E. Donald Tolles, 165 Broadway, New York.

National Electrical Manufacturers' Association—The Homestead, Hot Springs, Va., June 11-15. S. N. Clarkson, 420 Lexington Ave., New York.

Pacific Coast Division, N.E.L.A. — Hotel Huntington, Pasadena, Cal., June 12-15. S. H. Taylor, 447 Sutter St., San Francisco.

Georgia Electrical Association—Savannah, June 14 and 15. J. J. McDonough, Georgia Power Co., Dublin, Ga.

Northwest Division, N.E.L.A.—Portland, Ore., June 19-22. B. Snow, 1208 Spalding Bldg., Portland, Ore.

Canadian Electrical Association—SS. "Richelieu" from Montreal to Saguenay and return, June 20-23. H. M. Lyster, 712 Power Bldg., Montreal.

American Institute of Electrical Engineers—Cosmopolitan Hotel, Denver, June 25-29. F. L. Hutchinson, 33 West 39th St., New York.

Association of Iron and Steel Electrical Engineers—Hotel Stevens, Chicago, June 25-28. J. F. Kelly, Empire Bldg., Pittsburgh.

American Society for Testing Materials — Chalfonte-Haddon Hall, Atlantic City, N. J., June 25-29. C. L. Warwick, 1315 Spruce Street, Philadelphia.

East Central Division, N.E.L.A.—Cedar Point, Ohio, July 10-13. D. L. Gaskill, Greenville, Ohio.

New Hydro Development for Washington Coast. — Authority to proceed with the construction of a concrete dam across the North River near Brooklyn, Wash., just given by the Federal Power Commission, permits the Western Washington Electric Light & Power Company of Raymond to begin work on its hydro project, where it is said as much as 70,000 hp. may be generated. The federal permit was necessary owing to the fact that the North River, tributary to Willapa Harbor, is navigable in certain sections.

Floods Sweep a Small Quebec Plant and Three Dams Away.—The power plant of the Vanchesteing Electric Power & Light Company, at St. Jovite, Quebec, valued at $30,000, was washed away by floods which swept through the northern section of the Laurentian district recently. The floods resulted from the breaking of three power dams under the pressure of waters released by the melting of snow and ice. St. Jovite is about 75 miles north of Montreal.

To Harmonize Substation with Public Building Architecture.—The Union Electric Light & Power Company of St. Louis has awarded a contract for a substation to be erected on Clark Avenue, west of Fourteenth Street, at a cost of $200,000. The structure will be equivalent in height to an ordinary three-story building and has been designed to harmonize architecturally with the municipal and state building fronting on the St. Louis Memorial Plaza. The exterior walls will be of Bedford stone.

Tennessee Company Files Holston River Application. — The Tennessee Eastern Electric Company has filed application with the Tennessee Railroad and Public Utilities Commission to construct a dam and hydro-electric plant on the Holston River. The company agrees that the project shall be started within eighteen months after the issuance of the permit and shall be completed for operation within three years. It will cost $5,200,000. The dam, on the south fork of the Holston, would form a reservoir extending 8 miles up the Holston and 4 miles up the Wautauga River.

Court Denies Injunction to Halt Hydro Development on Kings and San Joaquin Rivers.—An injunction applied for by J. J. Stevenson, a corporation owning about fourteen thousand acres in Merced and Stanislaus Counties, Cal., and intended to restrain further development of power resources by the San Joaquin Light & Power Corporation on the Kings and San Joaquin Rivers, has been denied in the Superior Court at Merced. The plaintiff claimed that the power company's development was an infringement upon its rights to a continuous flow of these streams. If granted, the injunction would have affected the Crane Valley, Kerckhoff and Balch plants.

North Central Division Will Not Hold Convention This Year.—The North Central Electric Association, geographic division of the N.E.L.A., has decided to hold no convention this year. Instead it will hold conferences during the year in various parts of the district. The next of these—a managerial conference—will be held at Breezy Point Lodge, near Pequot, Minn., on June 15 and 16. Sixty reservations have already been made. Accounting, commercial and engineering conferences have already been held. The managerial conference will be the first of its kind to be held by this body.

More Interconnection in New Hampshire.—Preliminary surveys have been started by the Utilities Power Company for a 33,000-volt transmission line extending from Melvin Village to Center Ossipee, N. H. This 11-mile line will form on its completion a connecting link between the Laconia division of the Public Service Company of New Hampshire, the Utilities Power Company, the Franklin Light & Power Company and the Tilton Light & Power Company. The three latter companies are controlled by the New England Public Service Company and are operated by the Public Service Company of New Hampshire with headquarters in Manchester. Another survey will be started at once for an interconnection between the Garvins Falls plant on the Merrimac River, south of Concord, and the Bristol plant of the Utilities Power Company. The distance is 35 miles.

Indiana Men Meet Next Week.—The Indiana Electric Light Association will hold its annual convention at Indianapolis on May 22, the day before the Public Utilities Association of the state convenes. President Robert M. Feustel of Fort Wayne will preside, and Thomas F. English, South Bend, president of the Great Lakes Division of the N.E.L.A.; G. C. Neff, vice-president Wisconsin Power & Light Company, and C. V. Sorenson, vice-president Attica Electric Company and chairman of the Indiana rural electrification committee, will speak, the two latter on rural electrification. Truman E. Heinton will discuss the Purdue University short courses. Before the Public Utilities Association John B. Malling of Hammond, Ind., will speak on "The Government in Business" and Morse Dell Plain will read a paper on "The Training of Supervisory Forces." A member of the Indiana Public Service Commission will be invited to address the meeting and a round-table discussion on utility advertising will be held.

# Recent Court Decisions

Company Not Entitled to Damages When Compelled to Remove Wires from Vacated Alley.—In Northern Indiana Gas & Electric Company vs. Merchants' Improvement Association the electric company showed that it had occupied an alley in the city of Hammond with poles and electric light wires erected under a franchise grant from the city to supply its inhabitants with electricity. The alley was vacated by order of the board of public works, and the association, as the owner of abutting lots, brought action to enjoin the company from maintaining its poles and wires on the premises. The trial court found that the company should be enjoined from maintaining its poles and wires and that it was not entitled to damages because it was compelled to remove them from the vacated alley, and the Indiana Appellate Court has sustained this finding. (160 N.E. 50.)*

Evidence to Show Negligence on Two Counts, Notwithstanding Admission of One of Them by Defendant, Need Not Invalidate Trial.—Sustaining a judgment for injuries to a boy from a fallen wire (Martin vs. Pacific Gas & Electric Company), the Supreme Court of California found that a charge of negligence against the company based not only on its failure for several hours to remove the wire from the sidewalk where it fell but also on alleged failure to maintain it properly before it fell was not prejudicial or inflammatory. The defendant was willing to admit liability on the charge of not removing the fallen wire and contended that subsequent admission of testimony on this as well as on the unadmitted charge of faulty maintenance led to excessive damages being fixed by the jury. The Supreme Court held that the damages—$25,000—were not as a matter of law excessive, the boy having suffered what appeared to be great and permanent injury. (264 Pac. 246.)

Water-Power Rights Permit Increased Use in Public Interest.—When a hydro-electric utility finds it necessary to reconstruct its plant and appropriate additional water in order to maintain a service adequate to meet the demands of the public, such expansion does not interfere with the original water-power rights of the operator. This is a decision of the Hood River County (Ore.) Circuit Court involving water rights of the People's West Coast Hydro-Electric Corporation acquired from the West Coast Power Company. In 1919 the People's West Coast company reconstructed the plant and increased its power capacity. Before this was done the State Fish Commission issued an order closing Herman Creek to further appropriation except for the purpose of fish culture, and this suit was instituted by the commission in an effort to cancel the utility's water rights on the ground that the company violated the provisions of its original application by reconstructing and altering its plant and appropriating more water than the initial permit called for. The greater interests of the public must prevail in such instances, the court held.

Commission Rules Governing Transmission Lines Are Not Applicable to Private Roadway.—The Central Illinois Coal Mining Company brought action against the Illinois Power Company in the Illinois Appellate Court on the ground that an award of $14,100 under the workmen's compensation act was made against the plaintiff for the death of one of its employees who was killed when a 12-ft. pipe he was carrying came in contact with the power company's high-tension line at a height of 12 ft. over a roadway used by the victim. The coal company alleged that the employee's death was caused by the negligence of the power company in constructing and maintaining its line at an altitude lower than that required by the Illinois Commerce Commission. Sustaining the judgment of the trial court, the Appellate Court held that the rules and regulations of the commission prescribing the minimum height of wires did not apply to wires over private property and that the roadway in question, not being a highway, street, alley or right-of-way, came under that designation.

# Commission Rulings

High Bill Should Be Adjusted in Case Where Meter Was Read After Its Removal from Demolished Building.—The New Jersey Board of Public Utility Commissioners has decreed, in settling a complaint made against the Atlantic City Electric Company by the Dixie Candy Company, that an adjustment should be made of an unusually high bill covering a period when service was not received and based on the reading of a meter after its removal by house wreckers because of the failure of the utility company to read and remove it upon receiving notice that the building in which it was installed would be torn down. The board said it would not permit a discontinuance of service if, in payment of future bills, the consumer deducted an amount already paid under protest in excess of what the board had approved as a reasonable charge, the commission lacking authority to order a cash refund of the excess.

Application of Reproduction-Cost Theory to Land Values.—In authorizing an issue of bonds and capital stock under certain restrictions by the United Electric Power Company the Rhode Island Public Utilities Commission considered the cost of reproduction new less depreciation only for the purpose of determining whether the amount of capitalization for which authorization was sought bore a relation to or was in excess of its fair value. In the matter of land values the commission said: "We believe a proper application of the cost-of-reproduction theory is a determination by appraisal of the value of each parcel in accordance with the market value of other land similarly situated in the same locality and enjoying similar public improvements, but without regard to the purposes for which the property is used. To this should be added the broker's commission which usually obtains where such land is located and an item of 1 per cent for other transfer costs, which we believe to be amply adequate for such costs under the testimony in this and other similar cases."

# News About Men of the Industry

## *H. L. Doherty's Birthday Celebrated*

Henry L. Doherty's fifty-eighth birthday was celebrated by his employees with an elaborate carnival at the Hotel Astor, New York, Tuesday, May 15, at which more than 1,800 members of the organization and their guests were entertained with a program lasting from 4:30 p.m. to 1 a.m., utilizing the entire tenth floor of the hotel. A number of entertainers prominent in theatrical circles furnished the program of the evening. A telegram was received by Frank R. Coates from Henry L. Doherty expressing his pleasure at the celebration and his regret at not being able to be present.

*H. L. Doherty*

Mr. Doherty, who is at the Battle Creek Sanitarium, Battle Creek, Mich., convalescing from his recent illness, was the recipient of many messages of congratulation and felicitation. Mr. Doherty is head of the firm of Henry L. Doherty & Company and president of the Cities Service Company.

Henry Maulshagen, district manager of the Alabama Power Company at Gadsden, has been appointed manager of that company's western division with headquarters in Birmingham. Mr. Maulshagen served as superintendent of the company's steam plant at Gadsden prior to becoming district manager.

H. O. Clarke, Jr., assistant general manager of the Houston Lighting & Power Company, Houston, Tex., was elected second vice-president and chairman of the electric section of the Southwestern Public Service Association at the recent convention held in Dallas. Mr. Clarke has been associated with the Houston properties for a number of years.

Claude L. Matthews, vice-president and treasurer of the W. N. Matthews Corporation, St. Louis, Mo., arrived in Los Angeles May 15 to address a meeting of the electrical industry of southern California held at the Hotel Biltmore, having left Chicago the preceding day by airplane. Mr. Matthews carried with him messages of felicitation and greetings from power companies and electrical manufacturers of both Chicago and St. Louis to the electrical fraternity on the Pacific Coast.

James L. Tonge has been appointed distribution engineer of the Narragansett Electric Lighting Company, Providence, R. I.

William H. Lipscomb, formerly president of the Habirshaw Cable & Wire Corporation, New York, has been elected president of the Dubilier Condenser Corporation to succeed Fred D. Williams. Mr. Lipscomb, who also served on the directorate of the Habirshaw organization, was at one time identified with the United States Steel Corporation.

## *C. F. Brush Honored by Franklin Institute*

Charles F. Brush, engineer and inventor of Cleveland, was made the recipient on May 16 of the Franklin medal by the Franklin Institute of Philadelphia. This latest award is just another expression of esteem in a lengthy list of honors conferred upon Mr. Brush in the course of his scientific career. Among the outstanding examples of recognition are the decoration as Chevalier Legion d'Honneur (France) and the award of the Rumford medal by the American Academy of Arts and Sciences and the Edison medal by the American Institute of Electrical Engineers. Mr. Brush is especially noted for the Brush electric arc light, which he perfected and gave to the world in 1878, the system first having been adopted by the city of Cleveland and subsequently extending to all parts of the world. Later he contributed many other fundamental inventions in both arc and incandescent lighting, storage battery and other devices.

*C. F. Brush*

## *R. P. Stevens President of New Utility Company*

Ray P. Stevens, chairman of the board of Stevens & Wood, Inc., has been named president of the Allied Power & Light Company, the organization just formed from the consolidation of the interests of Hodenpyl, Hardy & Company, Inc., and Stevens & Wood, Inc. B. C. Cobb, vice-president of the Commonwealth Power Corporation and an operating official of other Hodenpyl and Hardy properties, will be chairman of the board of the new corporation.

*R. P. Stevens*

Mr. Stevens has long been an outstanding figure in the electrical industry. After he had built and operated a large number of electric light and power plants in the South he then, in the capacity of consulting engineer, designed and constructed at Everett, Wash., an entire new railway and a light and power system, of which he became manager. Transferring his interests to the East, he spent several years in central New York before removing to Allentown, Pa., where, during an administration that covered a period of six years, he effected a consolidation of eighteen light and power companies, which resulted in great benefits to the communities served. In 1913 he resigned as president of the Allentown companies to become president of the Mahoning & Shenango Railway & Light Company and its subsidiary companies with headquarters in Youngstown, Ohio, and at the present time is president of the Penn-Ohio Edison Company, which has just taken over the Northern Ohio Power Company. Mr. Stevens has been active in association work, being president of the A.E.R.A. and a member of the A.I.E.E., the A.S.M.E. and other technical organizations.

Ralph P. Ormsbee has been appointed assistant superintendent of distribution of the Narragansett Electric Lighting Company, Providence, R. I.

## *O. G. Thurlow Awarded Potts Medal*

Oscar G. Thurlow, vice-president and chief engineer of the Alabama Power Company, was made the recipient of the Howard N. Potts medal by the Franklin Institute in recognition of his work in inventing the Thurlow backwater suppressor. The medal is awarded by the Institute for distinguished work in science or the arts, important developments of previous basic discoveries, inventions of products of superior excellence or utilizing of important principles. This award is the second honor to be conferred upon Mr. Thurlow in recognition of his service to the study of science by the invention of the backwater suppressor and other engineering achievements. Last spring the University of Alabama conferred upon him the degree of doctor of science because of this accomplishment and because of his practical services in using it in the development of Alabama's resources.

*O. G. Thurlow*

Dr. Thurlow is a native of Massachusetts and a graduate of the Massachusetts Institute of Technology. He first came to Alabama in 1909 with the Tennessee Coal, Iron & Railroad Company and in 1912 he became associated with the Alabama Power Company. In addition to being vice-president in charge of engineering for this company he is also a member of the board of directors.

---

David Sarnoff, vice-president of the Radio Corporation of America, sailed for Europe May 5 aboard the *Leviathan*.

George E. Learnard, president of the International Combustion Engineering Corporation, sailed for Europe aboard the Cunard liner *Aquitania* May 9.

E. L. Callahan has been appointed general commercial manager of the Central Public Service Corporation with headquarters in Chicago. Mr. Callahan has had a long and varied experience in the electrical industry, his activities having extended into every department of the commercial side of central-station practice. Early in his career he was connected with Westinghouse, Church, Kerr & Company, the Simplex Electric Heating Company, the Prometheus Electric Company and the General Electric Company. So successful had he been in handling pioneer sales problems for the central station companies that he was selected by H. M. Byllesby & Company in 1909 to organize and direct the new-business department. He resigned six years later to become district manager of the Westinghouse Lamp Company in Chicago, subsequently being promoted to the position of sales manager of the company. Mr. Callahan has been active in association work, having been one of the founders and chairman of the Commercial Section of the National Electric Light Association and a frequent contributor to convention programs and to the technical press.

## *H. C. Blackwell Heads New Company*

H. C. Blackwell, formerly president of the Union Gas & Electric Company, Cincinnati, has been named president of the new Cincinnati Gas & Electric Company, the organization resulting from the merger of the Columbia Power Company, the Cincinnati Gas & Electric Company and the Union Gas & Electric Company. Mr. Blackwell is well known in national engineering circles, both as an executive of long standing of electric light and power companies in the Middle West and as an officer in the representative engineering societies. His early connections included the Wabash Railroad Company, J. G. White & Company and the People's Light Company at Davenport, Iowa, advancing in the last-named company from engineer to the position of vice-president and general manager. As vice-president and general manager of the Kansas City Power & Light Company in charge of construction and operations, he was closely identified with the Kansas City development, one of the most successful of the larger electric enterprises in the country.

***H. C. Blackwell***

In 1924 Mr. Blackwell removed to Cincinnati to become vice-president in charge of operations of the Union Gas & Electric Company, succeeding W. W. Freeman as president two years later.

## Obituary

Charles E. Merritt, assistant treasurer of the Commercial Cable Company, New York, for the past 27 years, died, of pneumonia, at his home in that city April 17. Mr. Merritt had been associated with the submarine cable industry in various capacities for the past 60 years. He was 82 years of age.

Raymond B. Keating, vice-president of the West Penn Electric Company and its major subsidiaries, died May 12 after a brief illness. Mr. Keating was born in Pittsburgh in 1880 and spent the greater part of his business life in that city. Early in his career he was identified with the Philadelphia Company, the Electric Properties Company of New York, the Lackawanna & Wyoming Valley Railroad Company, the Electric Power Security of Niagara Falls, New York, owned and operated by the Westinghouse Electric & Manufacturing Company, and the Merchants & Manufacturers' Exchange of New York City. In 1914 Mr. Keating became vice-president of the West Penn System at its New York offices and in August, 1915, returned to Pittsburgh to continue his active duties with this company. At his death he was vice-president of the West Penn Electric Company, West Penn Railways Company, West Penn Power Company, as well as their subsidiaries. He was also a director and vice-president of the Monongahela West Penn Public Service Company of Fairmont, W. Va.

Robert Wales Emmons, 2d, treasurer of the Lawrence (Mass.) Gas & Electric Company from 1903 to 1926, inclusive, died recently at Buzzards Bay, Mass.

Alvah W. Sulloway, for many years president of the Franklin Light & Power Company, Franklin, N. H., died April 23 at his home in that city, in his 90th year. Mr. Sulloway was born in Framingham, Mass., and after schooling entered the hosiery manufacturing industry, with which he was connected a great part of his life. He organized and was president of the Franklin National Bank from 1879 until the time of his death. He was also president of the Franklin Savings Bank. For many years he was a director of the Boston & Maine and Maine Central Railroads, president of the Franklin Light & Power Company and the Acme Knitting Machine & Needle Company and a director and officer in other enterprises. Mr. Sulloway was also active in state politics.

# Financial and Statistical News

## Westinghouse Electric Sales Totaled $175,456,815

Sales of Westinghouse Electric Company for the year ended March 31 last were $175,456,815. Net manufacturing profit amounted to $14,000,000 and net income available for dividends $15,600,000. Earnings per share on the preferred and common stock amounted to $6.57, or 13.4 per cent. Dividends were paid during the year on both stocks at the rate of 8 per cent per annum, or $4 per share of $50 par value. This represents a slight decrease in business as compared with the previous year, when sales totaled $185,500,000 and earnings amounted to $6.80 a share.

As of March 31 the company's balance sheet shows current assets aggregating $122,000,000, which is more than eight times current liabilities. The sum of $3,000,000 representing a federal income tax reserve no longer required was restored to surplus.

Approximately $40,000,000 has been spent in the past six years for new plants and extensions. All plants have been provided with modern facilities, and the company is now in a position to take care of a business, at present prices, of more than 25 per cent in excess of this year's shipments. A statement of earnings, operating costs, interest charges, etc., in comparison with those of last year is shown in the accompanying table.

| | 1928 | 1927 |
|---|---|---|
| Gross earnings | $175,456,815 | $185,543,087 |
| Costs | 161,347,356 | 169,764,086 |
| Net manuf. profit | 14,109,459 | 15,779,001 |
| Other income | 3,031,704 | 2,585,614 |
| Gross income | 17,141,163 | 18,364,615 |
| Interest, etc. | 1,501,991 | 2,226,174 |
| Net for dividends, etc. | $15,639,172 | $16,138,441 |

## Hartford Residential Service Analysis

The Harvard Graduate School of Business Administration, through its department of public utility management, has made an analysis of the residential electric business of the Hartford (Conn.) Electric Light Company covering the years 1914 to 1926, inclusive. After presenting the usual growth figures, the study proceeds to analyze by rate classification and by types of residential areas, giving actual billing records of the various groups, and includes particularly a study of the effect of promotional type rates and of appliance merchandising. For example, it was found that even in the better class of apartment house districts the use per customer was remarkably low. A commentary by Prof. Philip Cabot, reprinted from the *Annalist*, is appended. The report was prepared by J. Gardner Coolidge of the department's research staff; it is published as a 41-page pamphlet, of which copies are obtainable at a small charge from the department, Soldiers Field Station, Boston, Mass.

## Penn-Ohio Edison Capital

On completion of the exchange of Northern Ohio Power common stock for Penn-Ohio Edison common under the merger plan capitalization of the latter will comprise: $5,999,000 6 per cent debentures, $8,151,800 7 per cent preferred stock, 49,229 shares 6 per cent preferred stock, 717,003 shares common, 119,270 option warrants for purchase of common at $25 a share and 166,650 option warrants for purchase of common at various prices up to $60.

## Wyman Heads Portland Company

The New England Public Service Company has acquired from the National Electric Power Company substantially all the common stock of the Cumberland County Power & Light Company, Portland, Me. Out of 41,000 shares, only 35 are held outside. At a recent meeting of stockholders in Portland the following officers were elected: H. M. Verrill, chairman of the board; Walter S. Wyman, president; Fred D. Gordon, vice-president in charge of operations; F. D. True and George Otis Smith, vice-presidents; C. F. Berry, treasurer and clerk. George E. Haggas continues as chief engineer and Frank R. Fowles manager of the power and light department.

## Billion Dollar New York Merger at Last Ratified

### Brooklyn Edison Company Will Be Acquired by Consolidated Gas on Exchange of Stock if Stockholders and Public Service Commission Approve

THE long-anticipated and much-rumored merger of the Consolidated Gas Company of New York and the Brooklyn Edison Company has at last been ratified by the trustees of the former company and the directors of the latter. Conditions remaining to be fulfilled are: Approval of the Public Service Commission of New York, receipt of assent to the plan on the part of at least 70 per cent of Brooklyn Edison stockholders before June 15 and, of course, formal ratification by Consolidated Gas shareholders of capital structure changes necessary to accomplish the absorption. The plan involves acquisition of Brooklyn Edison common stock by Consolidated Gas on the basis of an exchange of one share common and one share $5 preferred of the latter company for one common share of the former.

Completion of the present merger plans will give Consolidated Gas Company of New York control of virtually the entire electricity and gas business of New York City, Westchester County and Long Island. The Brooklyn Union Gas Company, Staten Island Edison Corporation and Long Island Lighting Company remain independent. Reported heavy holdings by the Mellon interests in Brooklyn Union Gas and Consolidated Gas, as well as in United Gas Improvement of Philadelphia, suggest the possibility of a larger merger in the future.

From a statistical standpoint the present merger is one of large proportions. Assets of the Consolidated Gas system at the end of 1927 exceeded $842,000,000 and those of the Brooklyn Edison $170,000,000, bringing the total to more than $1,012,000,000. Gross revenues of the two systems for 1927 were $200,481,641. At current prices capital stocks of the group exceed $1,000,000,000. Combined net profits for 1927, after interest and taxes, amounted to $52,310,157. Connected horsepower of the Consolidated Gas system totals 3,450,000. Consolidated Gas properties last year sold 2,320,531,525 kw.-hr. and Brooklyn Edison sales were 754,635,609 kw.-hr., bringing the total to 3,075,167,134 kw.-hr. for the two systems. Combined earnings of the two companies will be equal to $4.04 a share.

A development which will probably follow the merger is the segregation of the gas and electric properties of the combined system with the formation of separate operating companies and a controlling holding company.

It is intimated that the Consolidated Gas Company common stock will be split on a two for one basis. At current prices this would bring the new stock to around $82 a share. Brooklyn Edison common is currently quoted around $262. Completion of the exchange would call for the issue of about 6,120,000 shares of Consolidated Gas common.

While substantial economies in various directions are anticipated from the merger, an official of Consolidated Gas Company informed the ELECTRICAL

WORLD that no definite action had yet been taken with regard to any possible reduction in rates. Other important details of joint operation yet remain to be worked out, while the financial set-up is being revamped along necessary lines.

## A Quarter Billion Horse-Power Utilized

The total capacity of all the power-generating equipment installed in the various industries in the United States in 1923, from the highest type of steam turbine and internal-combustion engine down to the erratic windmill and the farm-work animal, was 230,514,000 hp., exclusive of the horsepower of pleasure automobiles. It is an astonishing fact, says the Department of the Interior, which agency compiled these figures, that the total horsepower capacity of the internal-combustion engines of pleasure automobiles is nearly twice as much as that used in all the industries, the total capacity for 1923 inclusive of pleasure automobiles being 684,044 hp. This tremendous capacity, if converted into man-power, would furnish about 60 able-bodied servants in constant attendance on every man, woman and child in the United States. The horsepower of industrial prime movers in 1923 was distributed as follows: Manufactures, 9 per cent; mines and quarries, 2 per cent; agriculture, 17 per cent; electric central stations and electric railroads, 11 per cent; steam railroads, 32 per cent; ships, 4 per cent; work animals not on farms, 1 per cent; automobiles not classed as pleasure cars, 23 per cent; miscellaneous, 1 per cent.

The population of the United States increased 45 per cent from 1899 to 1923, while the capacity of industrial-power equipment increased 260 per cent. In 1849, 66 per cent of the total industrial power equipment of the country was installed in farms; in 1923, only 17 per cent, the greater part being utilized by steam railroads, manufactures, central stations, electric railways and automobiles other than pleasure cars.

These figures are taken from a report entitled "Power Capacity and Production in the United States," just published by the Department of the Interior as Water-Supply Paper 579 of the Geological Survey. It contains information about the capacity of the different types of prime movers installed in the industries in the United States from 1849 to 1923 and shows their relative growth by index numbers and by diagrams. The report also contains the monthly figures of production of electricity and consumption of fuel by public-utility power plants from 1919 to 1926, estimates of the potential water-power resources of the United States, and reports of the developed water power for different years which have previously been published by the Geological Survey in mimeographed form.

The information contained in the report has been collected in part by the Geological Survey in connection with its activities in studying the water resources of the country and their best utilization, in part by the Bureau of the Census in its periodic statistical study of the country's activities, and in part by the Federal Power Commission in connection with the administration of the federal water-power act. Some of the data have therefore been previously published in scattered statistical form, and some have been made available in multigraphed or mimeographed

preliminary reports, but some have never before been published. All these statistics are now brought together in such a form as to be available for further study and any other use that may be found to be desirable. They will serve as base data on which must rest any future study in this country of the problems of power utilization in relation to economics and government.

OUTPUT IN CANADA SHOWS INCREASE OVER LAST YEAR.—Output of power from central electric stations in Canada during the month of February was 1,273,982,000 kw.-hr., as compared with 1,317,882,000 in January and with 1,065,850,000 in February, 1927. This total includes both water and fuel developed power, the amount attributed to the former in February being 1,256,242,000 and to the latter 17,650,000 kw.-hr. Quebec stations continue to account for the majority of output, being credited with 603,303,000 kw.-hr., an increase of roughly 25 per cent over February of last year. Ontario was second with 462,441,000, followed by the Prairie provinces with 105,972,000 British Columbia, 87,882,000 and the Maritime provinces, 10,317,000. British Columbia reported a daily average of 3,028,000 kw.-hr. for February, as compared with 3,011,000 in January last and 2,610,000 in the same month of 1927. The total in the Maritime provinces equals that of March, 1927, which hitherto was the highest point ever reached by the Maritime stations. Exports of energy from Canada averaged about 4,300,000 kw.-hr. daily and have fluctuated but slightly in the past year or two. The amount is about 9 per cent of the total generated.

## Buffalo, Niagara & Eastern Adds to Directorate

Three new directors were elected at the annual meeting of the Buffalo, Niagara & Eastern Power Corporation, held May 8 in Buffalo. Lewis G. Harriman, Walter W. Huntley, and Hans Schmidt were added to the directorate to fill vacancies. Lewis G. Harriman is president of the Manufacturers & Traders-Peoples Trust Company and president of the Buffalo Chamber of Commerce. He is also connected as a director and officer with a number of Niagara frontier business organizations. Walter W. Huntley is also a director of the Niagara

Electric Service Corporation. For a number of years he was connected with the Buffalo General Electric Company, but later entered the contracting field. Mr. Huntley is now president of the Elmwood Construction Company, Inc., of Buffalo. Hans Schmidt has long been prominent in business and financial circles on the Niagara frontier. Mr. Schmidt is a director of the Niagara Falls Power Company and president of Schoellkopf & Company.

## Standard Gas & Electric Has Built Exceedingly Sound Structure

GRADUALLY extending its operations across the map of the United States, the Standard Gas & Electric Company has placed its imprint thereon at ten major points. One of the most romantic features of America's industrial progress during the past generation is the development of the power and light industry, the Standard Gas & Electric Company, with gross earnings from its system of slightly under $150,000,000 annually, has been no mean contributor toward this development.

In disbursements to shareholders this company has not been so liberal as have many other similarly situated holding companies. The average price of the parent company common stock in 1923 was $25. At a current price of about $72 its appreciation during the period has been exceedingly modest in comparison with that of other systems, such as American Power & Light, American Gas & Electric, American Water Works & Electric Company and others that could be mentioned, where stock splits have induced material enhancement in value. Standard Gas & Electric Company is among those which have intrenched themselves by turning back a large share of earnings into the system. Such a policy has built this group into one of the soundest utility systems in the country. Earnings last year on common stock amounted to $5.30 a share, against $4.68 the year before. This means that at a price of $70 the stock is worth about thirteen times earnings, which is considerably under the average for power and light holding companies. The property investment of the system is approximately $5.75 per dollar of gross revenue.

The financial year 1927 was a very profitable one for the Standard Gas & Electric System. Taking the holding company alone, the gross revenue amounted to $13,124,130, and of this $12,881,008 was net revenue. This is an increase of approximately 20 per cent both in gross and in net. For the system as a whole the gross earnings from the company's public utility properties amounted to $145,953,139, and net earnings were $63,145,163, which indicates an operating ratio of 56 per cent, against almost 58 per cent in 1926. There is a balance available for common stock equivalent to $6.60 a share on the average amount of common stock outstanding. The parent company pays a dividend of $3.50 on common stock.

Oklahoma Gas & Electric

*Standard Gas System widely diversified geographically*

The financial set-up of the Standard Gas & Electric Company is in an unusually strong position. Common stock totals 1,418,803 shares of no par value. The surplus shown in the most recent balance sheet is $12,166,135. There are three issues of preferred stock, one 6 per cent, one 7 per cent and one 8 per cent, aggregating $48,274,000 in book value. The funded debt also comprises three separate issues, all bearing 6 per cent and totaling $40,000,000 book value. The company again established a new record in 1927 in the sale of preferred stock to customers. The par value of sales totaled $31,975,600, which is 27 per cent higher than the 1926 total. Approximately 22,000 new shareholders were added during the year, a factor of importance in the company's public relations.

During the year many of the company's subsidiaries took advantage of the low money rate and a satisfactory market for power and light securities to accomplish refunding operations with resulting large savings in interest and dividend charges.

## New Public Utility Financing Active

Eight new offerings were made by electric light and power companies during the week ended May 17, two in the form of debentures, five in the form of gold bonds and one in the form of gold notes. The American Commonwealths Power Corporation issued 5½ per cent gold debentures to the amount of $4,500,000 at 96½ and interest to yield over 5.75 per cent. The American Gas & Power Company made an offering of secured gold debentures at 95½ and accrued interest, to yield over 5.30 per cent, a piece of financing involving a total of $6,500,000.

Two new offerings were made by the Public Utilities Consolidated Corporation, the two issues totaling $5,500,000. One issue was in the form of ten-year 6 per cent secured convertible gold bonds priced at 98 and accrued interest and the other in the form of first mortgage twenty-year 5½ per cent gold bonds priced at 97 and accrued interest.

Twenty-five year 5½ per cent sinking fund secured gold bonds, series A, of the Islands Edison Company were issued to the amount of $2,250,000 at 96 and accrued interest, to yield 5.80 per cent.

First mortgage and refunding 5 per cent gold bonds of the Indiana Electric Corporation were offered to the amount of $3,268,000, the price being 100 and interest. The Electric Public Utilities Company made an offering of three-year 5 per cent gold notes at 97¼ and interest, amounting to $3,000,000.

The unexchanged portion of a new issue of $35,000,000 Associated Gas & Electric Company debenture bonds, amounting to $8,750,000, were offered at par and interest to yield 5 per cent.

RECENT LISTINGS.—The Baltimore Stock Exchange has authorized the listing of 5 per cent cumulative preferred stock, series A, of the Consolidated Gas, Electric Light & Power Company of Baltimore (par $100) to the amount of $15,500,000 and of 4½ per cent, series B, first refunding mortgage gold bonds of the Pennsylvania Water & Power Company to the amount of $6,000,000. The Boston Stock Exchange has authorized the listing of first mortgage sinking fund gold bonds, 6½ per cent series, due 1953, of the Electric Power Corporation (Elektrowerke Aktiengesellschaft) to the amount of $5,000,000 and additional 6 per cent convertible gold debentures of the Peoples Light & Power Corporation totaling $750,000.

# Business News and Market Conditions

## N.F.P.A. Accepts 1928 Code

*Rules Virtually Same as Advance Publication Report of Electrical Committee—Recognition Given to Increased Use of Higher Voltages in Wiring Work*

AT SIX well-attended sessions of a special meeting of the electrical committee of the National Fire Protection Association at Atlantic City, N. J., this month the 1928 National Electrical Code was approved subject to a letter ballot of its members. The electrical committee meeting was preceded by a three-hour meeting of the correlating committee which was appointed at the February, 1928, meeting of the electrical committee, the agenda for that meeting being too extensive for its complete disposal during the time available.

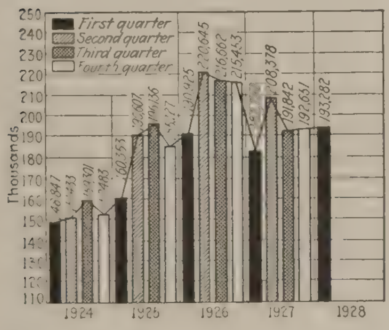
At the annual meeting of the N.F.P.A. held at Atlantic City on May 7, 8, 9 and 10 an enthusiastic reception was accorded the electrical committee's report. The report was approved by the N.F.P.A. subject to a letter ballot of the members of the electrical committee, after which it will be sent to the executive committee of the N.F.P.A. and later to the American Engineering Standards Committee. It is thus expected that the 1928 code will be available for distribution in the early fall.

Substantially all the rules as submitted by the correlating committee were adopted by the electrical committee and virtually all the articles were approved unanimously. Under the head of definitions the term "extra hazardous location" was omitted and the definition applying thereto was combined under the head "hazardous location." Article 5, wiring methods, as well as article 9, grounding, came in for a good deal of discussion. In article 6, conductors, a very helpful development has been added in the way of providing larger circuits in dwellings and encouraging more circuits to provide for the greater use of appliances. The rules for electrical metallic tubing, under article 5, remained virtually the same as published in the advance publication report of the electrical committee covering the proposed 1928 National Electrical Code.

In article 50, circuits and equipment operating at more than 600 volts between conductors, provision was made under rule 5009, service equipment, to permit the use of other than oil circuit breakers if such devices are developed and found suitable and will satisfy the interest of the code. The section devoted to automatic overload circuit breakers under this rule also was expanded. In general, article 50 was considerably expanded, both in number of items and treatment, to keep in step with the considerable increase of the use of higher voltages in wiring work.

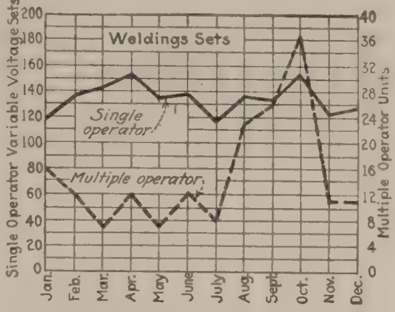
At the annual meeting of the N.F.P.A. A. M. Schoen, chief engineer of the Southeastern Underwriters' Association of Atlanta, Ga., was elected president.

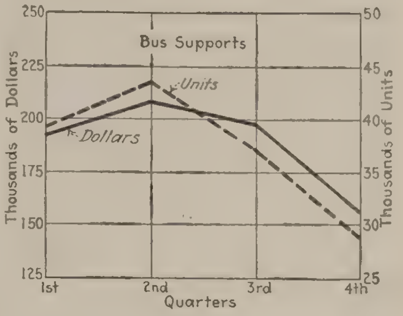
## Sales of Electric Washing Machines by Quarters

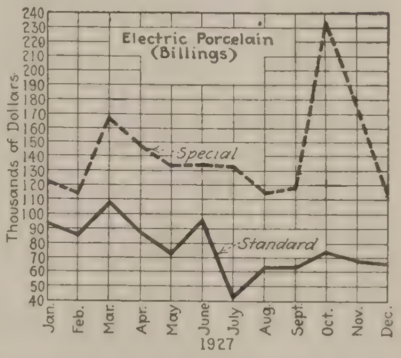


NOTE—March sales figures showed a substantial gain over those of February.

## N.E.M.A. Statistics







Other data covering 1927 appeared in preceding issues.

# Market Conditions

DISTINCT optimism as to the business outlook pervades the electrical field and current business is in good volume. In New England many small orders were placed. Motor sales amounted to about $50,000. Central-station companies are buying wiring material steadily in small lots. The demand for motors in the Eastern district is strong and some sizable bookings are expected to mature in the next 30 to 60 days. A manufacturer of gypsum products will soon make commitments for new plants to cost more than $1,000,000; a copper company will make purchases for a proposed refinery to cost $4,000,000, while another copper interest in Utah will electrify at a cost of over $1,000,000. A washing machine manufacturer placed an order for $20,000 worth of motors and a maker of talking machines ordered disk type motor units amounting to $30,000. Railroads have purchased over $300,000 worth of equipment.

An order for four 40,000-kw. vertical water wheel generators was placed in the Southeast for a development in North Carolina. An order for power transformers from the same state amounted to $50,000. Industrial plant business also is active. In St. Louis spotty business is reported. The volume of sales is good in the Middle West, and utility companies continue active with construction work. On the Pacific Coast power company business is good and industrial plant buying is active. New steel plants in Los Angeles and San Francisco, a lumber mill at Klamath Falls, an automobile body plant in Seattle, a seed plant and warehouse in San Bruno and a terminal for San Francisco produce and provision wholesalers are active projects involving more than $10,000,000.

## Metal Market Active—Prices Higher—Lead Steady

Exceptionally active sales of copper with an advance in price took place in the non-ferrous metal markets. With the exception of lead which is steady prices have shown an advance. Copper producers have advanced their price from 14¼ cents to 14⅜ cents per lb. delivered Connecticut Valley basis. Effective May 15, Copper Exporters, Inc. advanced their copper price from 14.50 cents to 14.625 cents per lb. c.i.f. usual European destinations. Lead has been quiet with a few sales at price concessions below the prevailing market levels. Tin is easy with a good demand for spot metal.

NEW YORK METAL MARKET PRICES

| | May 9, 1928 Cents per Pound | May. 16, 1928 Cents per Pound |
|---|---|---|
| Copper, electrolytic..... | 14.025-14.05 | 14.15-14.175 |
| Lead, Am. S. & R. price | 6.10 | 6 10 |
| Antimony.............. | 11⅜ | 11⅜ |
| Nickel, ingot........... | 35 | 35 |
| Zinc spots............. | 6.325 | 6.40 |
| Tin, Straits............ | 51.875 | 52½ |
| Aluminum, 99 per cent... | 24.30 | 24.30 |

Base copper wire price May 16, 1928, 16⅛ cents.

## Motor Demand Strong in Eastern District

The call for motors for industrial service is active in the Eastern district and transactions are reaching a higher level than in several weeks. Sizable bookings are expected to mature during the next 30 to 60 days. Motor units of a wide range in horsepower rating are enjoying a good market. A manufacturer of gypsum products will soon make commitments for three new plants to cost more than $1,000,000; a copper company will make purchases for a proposed $4,000,000 refinery, while another copper interest will electrify its surface properties in Utah and is placing orders for equipment of various character, including electric mine locomotives, to cost upward of $1,000,000. A manufacturer of washing machines in Northern New York has contracted for a quantity of ⅛-hp. motors, with a leading producer, totaling about $20,000. A maker of talking machines in New Jersey has placed an order for disc type motor units with the same manufacturer, at $30,000.

An order for motor and control equipment for a New York subway extension has been placed at a price of $175,000. A steam railroad in the same city has contracted for similar apparatus, for its electric system, totaling about $80,000. A Middle West steam line has purchased electric drive equipment for gasoline car service to an amount of about $35,000. Central-station business is a little spotty, with the bulk of orders centered in substation and affiliated equipment. A New Jersey utility has contracted for a quantity of feeder regulators, totaling $45,000. Another Eastern utility has placed an order for a sizable quota of bus supports and units of indoor type. A number of good contracts for similar apparatus are now pending. Instrument business is improving and inquiries are increasing both in volume and individual account.

Sales of electric appliances are lagging. Jobbers both in the New York and Philadelphia districts report business as unsatisfactory. Low prices and the tendency to cut below normal margins, coupled with keen competition, are making for a spotty situation which does not show signs of immediate betterment. Construction operations in the Eastern district includes the following:

The United Electric Light & Power Company, New York, will build a storage and distributing plant to cost $50,000. The Harlem Valley Electric Corporation has taken over the Carmel (N. Y.) Light & Power Company. The Purty Boat Works, Port Washington, N. Y., will erect a boat-building and repair plant to cost $150,000. The Nichols Copper Company, Laurel Hill, L. I., is arranging financing in amount of more than $4,000,000, for a new refining plant. The Atlantic City Electric Company is negotiating for the purchase of the municipal power plant at Beach Haven, N. J.

The Pennsylvania Railroad Company, Philadelphia, plans a cold storage plant to cost $1,000,000. The United States Gypsum Company, Chicago, plans a plant at Philadelphia to cost in excess of $300,000. Walker Brothers, Philadelphia, will build an electric equipment manufacturing plant at Spring Mill, Pa. to cost $80,000. County Commissioners, Pittsburgh, Pa., will receive bids until May 23, for ornamental cast iron light brackets. The Pusey & Jones Corporation, Wilmington, Del., will make additions in paper-making machinery plant to cost $350,000. The Annapolis & Chesapeake Bay Power Company has acquired the Herald Harbor Power Company and the Severna Electric Company, Anne Arundel County, Md. The Bureau of Supplies and Accounts, Navy Department, Washington, D. C., will receive bids until May 29, for insulated wire and cable for Eastern and Western yards (Schedule 9060).

## Large Generator Order Placed in Southeast

The largest power company order placed in the Southeast was for four 40,000-kw. vertical water-wheel generators for a hydro-electric development in North Carolina. Another order from the same state was for large power transformers amounting to $50,000. A Georgia company ordered copper wire amounting to $16,500 and distribution and small power transformers totaling $14,500. Some other central-station orders were for watthour meters amounting to $4,800 and creosoted pine poles costing in excess of $3,600. An order for large power transformers aggregating $200,000 is in immediate prospect and will undoubtedly be placed in a few days.

A Georgia municipality ordered a 5,000-kw. turbine and switchboard, and an oil company in Louisiana ordered a turbine of the same size. A cotton mill in Georgia ordered $3,000 worth of wiring materials and lighting fixtures for re-lighting its mill. Engineers are working on plans for a rayon plant in Virginia for which two 2,500-kw. turbo-generators and other equipment aggregating $100,000 will be required. Bids for the equipment in that plant will be asked in about three weeks. A 40,000-spindle cotton mill to be constructed in Alabama will require electrical materials amounting to $75,000. The building contract for that mill will be let within six weeks. Engineers also are working on plans for a tobacco by-product plant to be constructed in Kentucky. Construction projects are as follows:

The Alabama Mills Company, Birmingham, will build mills in different parts of the state to cost $3,000,000. The Gould Tire & Rubber Company, Tampa, Fla., plans a mill to cost $150,000. Greenville, Miss., plans a municipal power plant. The Hudson Silk Hosiery Company, Charlotte, N. C., plans a mill to cost $300,000. The Crisp County Power Commission, Cordele, Ga., will receive bids on July 10, for a hydro-electric power plant on the Flint River, to cost $1,000,000. The Tennessee

Eastern Electric Company, Johnson City, Tenn., has applied for permission to build a hydro-electric power plant on the Holston River, to cost $5,000,000. The Jarman Shoe Company, Nashville, Tenn., plans a plant to cost $150,000. The constructing Quartermaster, Fort Monroe, Va., will receive bids until May 28, for a lighting system at the Langley flying field, Va. The Bristol Gas & Electric Company, Bristol, Tenn., will make extensions in its transmission and distribution system to cost $500,000.

The Appalachian Electric Power Company, Charleston, W. Va., plans a substation near Williamson, W. Va., to cost $150,000. The Alabama Power Company, Birmingham, Ala., has acquired the power plant of Millport Gin, Ice & Power Company, Millport, Ala. The Southern Cities Power Company, Chattanooga, Tenn., plans a transmission line from Selma to Waynesboro, Tenn. The Virginia Electric & Power Company, will build a transmission line from Quantico to Occoquan, Va., to cost $150,000.

### *New England Places Small Orders in Good Volume*

Small motor orders in the New England district were encouraging and amounted to about $50,000. A number of these orders included general purpose motors for power in reorganized shoe and leather working plants, and textile mills also ordered a number of loom motors. Control equipment business was steady, with one consisting of switchboard apparatus amounting to $5,000 being reported. Several small orders for sub-station equipment amounting to $8,000 also were recorded.

Central stations are buying steadily in small lots, and wire, pole line material and insulators are in good demand due to numerous short extensions of service lines. A number of arc welders recently were placed in eastern Massachusetts, and sales of welders so far this year are above those of last year. Electric furnaces are in demand though negotiations are slackening. Contractors power tools are in strong demand and orders are being considered for extensive equipment for a large state water supply contract. Equipment for twelve large electric service elevators has been ordered at a cost of about $25,000. Construction projects are as follows:

A 33,000-volt line, 11 miles long, will be built by the Public Service Company, New Hampshire, connecting Melvin Village with Center Ossipee. A transmission line approximately 33 miles long is planned between the Bristol Falls plant and Bristol by the Utilities Power Company, New Hampshire. The Blackstone Valley Gas & Electric Company, Pawtucket, R. I., plans an addition to its power plant, to cost $120,000.

### *Spotty Business Reported in St. Louis District*

Business in the St. Louis district has been decidedly spotty. An order for wiring equipment in a federal building amounted to $6,000. Two fair-sized electric signs were sold at a cost of $2,000 each. Sales of stock apparatus has been below normal. Construction projects are as follows:

The Cowden Manufacturing Company, Kansas City, Mo., will build a garment factory to cost $130,000. The Chevrolet Motor Company, Detroit, plans an assembling plant near Leeds, Mo., to cost $1,000,000. The Union Electric Light & Power Company, St. Louis, plans a substation to cost $200,000. The Phillips Petroleum Company, Bartlesville, Okla., will make additions in its gasoline refining plants in Panhandle district of Texas, to cost $350,000. The American Potash Company, Dallas, Tex., plans a plant near Odessa, Tex., to cost $200,000. The Oklahoma Portland Cement Company, Oklahoma City, Okla., is planning a cement mill near Saratoga, Ark., to cost $500,000.

Olathe, Kan., is planning a municipal power plant. The Pumicite Company, St. Louis, plans plants at Stanley, Meade, Wilmore and Fowler, Kan., to cost $125,000. Boonville, Mo., will soon take bids for an addition to its municipal power plant. Campbell, Mo., will receive bids until June 5, for a municipal power plant to cost $40,000. The Arkansas Power & Light Company, Little Rock, Ark., has acquired the Southern Edison Company, Searcy, Ark. The Oklahoma Gas & Electric Company, Oklahoma City, Okla., plans a transmission line to Elmore City, Okla. The Central Power & Light Company, San Antonio, Tex., has acquired the Nixon Electric Light & Power Company, Nixon, Tex. Baton Rouge, La., will receive bids on May 29, for an ornamental lighting system. Fort Worth, Tex., plans an ornamental lighting system.

### *Volume of Business Good in Middle West*

Industrial activity in the Middle West is somewhat sluggish although the volume of business transacted is quite substantial. General movement of commodities, as indicated by carloadings, is less, but lack of movement of coal largely accounted for this condition. The various utility companies are busy with a good deal of construction work. Among the interesting orders placed were included two live steam reheaters, one feed water heater, one low pressure and one intermediate pressure closed feed water heaters, one portable oil purifier, 7,000 5-amp. watthour meters, 275 direct current watthour meters, 5 to 600 amp. capacity, a quantity of current transformers and Mazda lamps valued at $250,000. Jobbers' sales are increasing slightly. Construction projects are as follows:

The General Tire & Rubber Company, Akron, Ohio, will build a factory and distributing plant at Chicago, to cost $250,000. Evanston, Ill., plans a municipal power plant, to cost $65,000. The Bliss & Laughlin Company, Harvey, Ill., plans an addition to its shafting factory to cost $100,000. The Morgan Dyeing & Bleaching Company, Rochelle, Ill., will build an addition to cost $75,000. The Thieme Brothers Company, Fort Wayne, Ind., plans an addition to its knitting mill, to cost $115,000. The Southeastern Indiana Power Company, Indianapolis, Ind., is arranging for the purchase of the Eastern Light & Power Company, the Suburban Light & Power Company and the Evans Electric Company in Marion, Johnson, Fayette and other counties. The Chrysler Corporation, Highland Park, Mich., will build additions to its automobile plant, to cost $300,000, including a power plant, to cost $80,000. E. I. du Pont de Nemours & Company, Wilmington, Del., plans an ammonia plant at Barksdale, Wis., to cost $400,000. Superior, Wis., plans an airport lighting system. The Wisconsin-Michigan Power Company, Appleton, Wis., will build a transmission line from Iron River to Phelps, Mich. The Interstate Power Company, Oelwein, Iowa, will make extensions in transmission lines at Westbrook, Minn. The Montana-Dakota Power Company, Minneapolis, Minn., plans extensions in transmission lines at Tappen, N. D. Cedar Rapids, Iowa, plans a call for new bids for an ornamental lighting system following the rejection of bids recently received. St. Paul, Minn., and Lincoln, Neb., plan an ornamental lighting system.

### *Industrial Business Active on Pacific Coast*

Power company business has included orders for two carloads of steel guy strand, four carloads of poles and $2,500 worth of special steel pins. The Pacific Gas & Electric Company intends to spend $12,000 for rebuilding portions of its San Rafael to Petaluma transmission line. The United States Reclamation Service is requesting bids for a 19-mile, 66,000-volt, single power line and a 13-mile telephone line in the Nyssa (Ore.) district. Industrial business both actual and projected is excellent.

New factories projected include steel plants in Los Angeles and San Francisco for the Bethlehem Steel Corporation, a lumber mill and plant for Klamath Falls, a $2,500,000 plant in Seattle for the Fisher Body Corporation, a complete seed plant and warehouse in San Bruno and a $3,000,000 Marina district terminal for San Francisco produce and provision wholesalers. Street lighting business is very good.

The Seattle City Council has passed ordinances covering about $500,000 worth of work on its distribution lines. Ellensburg, Wash., has authorized an expenditure of $35,000 for improvements to its municipal plant. The port of Seattle plans a grain elevator to cost $1,500,000. Sales reported by jobbers include about $5,000 worth of transformers to local central-station companies, approximately 100 motors from 60 hp. down to industrial plants and $3,000 worth of pulleys for lumber mill drive. Construction projects are as follows:

Yuma, Ariz., is arranging to acquire the electric, gas and water utilities for $300,000, and will make extensions to cost $250,000. The Pacific Gas & Electric Company, San Francisco, has applied for permission to construct a hydro-electric power plant on Mokelumne River, near Jackson. A. M. Castle & Company, 1132 Blackhawk Street, Chicago, will build an iron and steel works at Los Angeles, to cost $350,000. The Montana Gypsum Products Company, Lima, Mont., plans a mill to cost $100,000.

The Royal Crystal Salt Company, Salt Lake City, Utah, plans a plant to cost about $500,000. The Centralia Lumber & Manufacturing Company, Centralia, Wash., plans a mill to cost $100,000. The Richfield Oil Company, Seattle, Wash., plans a plant to cost $200,000. San Jose, Torrance, Salinas, Culver City, Modesto and Santa Paula, Calif., plan ornamental lighting systems.

# Activities of the Trade

## Westinghouse Gets Order for Large Heating Equipment

Orders recently have been received by the Mansfield works of the Westinghouse Electric & Manufacturing Company for what is believed will be the largest installation of core baking ovens. The equipment goes to the New Zealand Government Railways, having been placed through Turnbull & Jones, Ltd., of Wellington, New Zealand, and the Westinghouse International Company. The complete installation will consist of a solid bank of baking compartments, ten in all, varying in width from 7 to 16 ft. The total width is 115 ft. Each compartment is 19 ft. long by 7½ ft. high.

Electricity will be used for heating the ovens, the heaters having an installed capacity of 1,185 kw. distributed through 192 5-kw. and 90 2½-kw. units. The order includes ovens, heaters, indicating and recording control panels and instruments for automatically controlling the temperatures in the compartments, motor blowers, transformers, ammeters and watt-hour meters. Bristol controlling instruments and American Blower Company motor blowers will be used.

The A. J. Lindeman & Hoverson Company, Milwaukee, manufacturer of electric cooking and heating appliances, announces the new "L & H" electric storage type water heaters which are automatically controlled by a mercury switch contactor actuated by a helical thermostat.

The Celoron Company, division of the Diamond State Fibre Company, Bridgeport, Pa., in conjunction with the opening of its new laboratory, and the introduction to the electrical, radio and automotive fields of Celoron molding compounds, announces the appointment of R. W. Wales as factory representative on molding powders and resins.

The Union Metal Manufacturing Company, Canton, Ohio, has received a contract from Seattle, Wash., for 538 twin-light standards 23 ft. high. The standards are of special design and construction and will embody the new type of fluted steel pole which was recently announced by the company.

The Eureka Vacuum Cleaner Company, Inc., Cleveland, has issued a 36-page folder embodying a sales plan for the "Premier" dealer. The plan covers a complete description of the new line of advertising and dealer sales helps for 1928.

The Chisholm-Moore Manufacturing Company, Cleveland, manufacturer of chain hoists and trolleys, traveling cranes and electric hoists, announces that the Columbus McKinnon Chain Company, Tonawanda, N. Y., has acquired control of its hoist division. The general sales offices and factory will continue to operate at Cleveland, under the same name as in the past. S. H. Moore, who has been with the company for the past 30 years, will continue with the organization and the personnel as a whole will remain the same.

The Foxboro Company, Inc., Foxboro, Mass., manufacturer of indicating, recording and controlling instruments, has established a branch office at 2104 Magnolia Building, Dallas, Tex., with J. B. McMahon as district manager. He will have as his associates R. L. Mallory and C. L. Bryan. The Dallas territory includes the states of Texas and Louisiana and the southern sections of New Mexico and Arkansas.

The General Electric Company announces price reductions on its popular types of "Mazda" flashlight, radio panel, toy train, mine and hand lantern lamps. These reductions, the company states, have been made possible through improvements in manufacturing processes and will mean a saving to the consumer of about 20 per cent in his future purchases. Since 1924 prices on miniature "Mazda" lamps, including lamps for automobiles, have been reduced approximately 50 per cent. During the same period motor vehicles have been reduced in price about 12 per cent, while all commodities have increased 62 per cent in price.

The W. N. Matthews Corporation, St. Louis, manufacturer of electrical specialties and mechanical painting equipment, announces the removal of its Chicago office to 9 South Clinton Street, Madison Terminal Building, Room 720, on May 1. H. L. Brueck is district manager. The company also announces that E. B. Josler, formerly with the Central States General Electric Supply Company, has recently joined its Chicago organization.

The National Flue Cleaner Company, Groveville, N. J., manufacturer of soot blowers for fire tube boilers, announces the appointment of the following representatives: Walter G. Heacock Company, 30 Euclid Arcade, Cleveland, and 413 Penobscot Building, Detroit; the Jack Deerwester Company, 1621 University Avenue, St. Paul, Minn.; Charles Zinram, P. O. Box 487, Erie, Pa., and the Laib Company, Louisville, Ky.

The Truscon Steel Company, Youngstown, Ohio, announces that it has purchased the Hydraulic Pressed Steel Company, Cleveland, which will be operated as its pressed steel division. The company states that the entire plant is being completely modernized and with the increase in facilities it will have one of the largest capacities for furnishing pressed and deep drawn steel of every description.

## Williams Oil-O-Matic Adds Refrigerator to Line

An electric refrigerator known as the Williams "Ice-O-Matic" has been placed on the market by the Williams Oil-O-Matic Heating Corporation, Bloomington, Ill. The "Ice-O-Matic" is furnished in boxes of from 5 cu.ft. to 20 cu.ft. food storage capacity and retails at $200 to $260 for the machine and $310 to $515 for the box and unit. Five different cabinet models are available. The refrigerating unit uses methyl chloride.

The same two-cylinder heavy-duty compressor is used on all jobs, the cooling unit or evaporator varying with each size. The units will be sold under the same terms as "Oil-O-Matics" are sold to the dealers and the distribution will be offered first to regular "Oil-O-Matic" dealers. During April the company conducted a special sales drive to introduce the unit. On June 25 and 26 the company will hold its fourth international convention.

The Ideal Commutator Dresser Company, Sycamore, Ill., announces the appointment of the Superior Supply Company, Bluefield, W. Va., as its sales representative for the sale of Ideal commutator resurfacers and other maintenance equipment in the Bluefield territory.

Landers, Frary & Clark, New Britain, Conn., manufacturer of electrical appliances, announce that they have withdrawn from sale the electric heating devices branded "Thermax" and "Reliance." The company is now offering in their place the new "Universal" popular priced electric appliances and at the same time is retaining the higher priced "Universal" appliances.

The Benjamin Electric Manufacturing Company, 128 South Sangamon Street, Chicago, has placed on the market a new dust-tight glass cover developed to meet the demand for a lightweight, economical device that will guarantee the original efficiency of lamps and reflecting surfaces, and a new hand portable inspection light designed especially for very close inspection work.

The Robbins & Myers Company, Springfield, Ohio (W. J. Myers, receiver), manufacturer of electric motors, generators and fans, announces that its New York office and warehouse are now combined and are located at 200 Varick Street.

Hatheway & Company, Inc., 16 Hudson Street, New York City, announces the removal to larger quarters at 225 Varick Street. The company is a national distributor for the Rattan Manufacturing Company, the Clifton Conduit Company, the A. E. Rittenhouse Company, the Clifduct Company, and the Superduct Company as well as local distributor for the Wirt Company, the Royal Electric Company and the Heinemann Electric Company. The Hatheway-Paterson Company, associated with Hatheway & Company, Inc., and representing the Gulf Cross Arms Company and the Bell Lumber Company, has also moved to 225 Varick Street, New York City.

The Trumbull-Vanderpoel Electric Manufacturing Company, Bantam, Conn., manufacturer of "T V" safety switches, etc., announces that Ralph Mason has been elected vice-president in charge of sales. Mr. Mason has been identified with the company since 1913.

The Rollway Bearing Company, Inc., Syracuse, N. Y., announces the appointment of Alfred E. Munch, Jr., as its representative in the Chicago-Milwaukee district, with headquarters at 544 Railway Exchange Building, Chicago.

Copeland Products, Inc., Detroit, manufacturer of electric refrigerators, announces that April shipments showed an increase of 41 per cent over the best previous month in the company's history.

# New Equipment Available

## Transposition Conduit

The "Natco" transposition conduit, to assist in meeting certain underground construction problems, has been placed on the market by the National Fire Proofing Company, Pittsburgh, manufacturer of "Natco" underground clay conduit. This new shape of conduit provides a means of transposing the position of ducts and cables in six-way, three-way or two-way multiple duct lines a quarter turn or 90 deg., or from an edge to a flat position or vice versa, in a distance of only six lineal feet. It also provides a means of transposing such duct lines and cables a half turn or 180 deg., or from a top to a bottom position or vice versa, in a distance of only twelve lineal feet.

It is supplied in six-way, three-way and two-way multiples in 24-in. lengths and each piece has a 30-deg. twist. "Natco" transposition conduit is used in building approaches to manholes or to central offices, where it is desired to change the position of cables in already existing duct lines, before entering such structures, thus avoiding the bending and crossing of cables therein. It also provides a means of changing the over-all height of conduit lines to avoid underground street obstructions or for bridge crossings.

## Portable Oil-Testing Set

A portable set for testing the dielectric strength of transformer and circuit-breaker oil has been placed on the market by the Westinghouse Electric & Manufacturing Company. The set is light and compact and may be easily carried by one man. The case is of cast aluminum with a hinged cover so arranged that it may be removed entirely if desired. When the cover is thrown back the complete control equipment is easily accessible and the set is ready for service.

The set consists of a small testing transformer inclosed in a cast aluminum case and covered at the top by a "Micarta" panel which carries the voltmeter and the control equipment. Two high-voltage bushings are brought through the panel and form the support for the oil testing cup. The voltmeter, mounted flush with the panel and calibrated in kilovolts, indicates the breakdown value of the oil. The transformer used is designed so as to eliminate surges in the high-voltage winding and the method of control used for obtaining variable voltages does not cause any distortion in the wave form. As a special safety feature, a push button is furnished, mounted in a depression in the panel, with the control so arranged that this button must be held down during tests in order to obtain voltage at the terminals of the testing cup.

## Clutch-Type Split-Phase Refrigerator Motor

A clutch-type split-phase refrigerator motor in which the starting current has been reduced to from 12 to 15 amp. has been placed on the market by the Day-Fan Electric Company, Dayton, Ohio. The efficiency and power factor also have been increased over those of the present repulsion-induction motors. The company states that the clutch which has been added to the motor is very dependable and has fewer working parts than are found on some brush-lifting devices. This motor is said to be a development of several years experience and a great number are now in operation. The manufacturer claims for the motor quietness, extraordinary efficiency in operation, high power factor, does not use brushes and does not introduce radio interference.

## Disconnecting Switch

An improved form of single-pole disconnecting switch has been placed on the market by the General Electric Company for outdoor service in voltages from 7,500 to 154,000 with a minimum current rating of 600 amp. The new switch has extra large break distances. It is assembled on cemented cap-and-pin type insulators and is designed for horizontal or vertical mounting. It is known as the type FA-1.

The tongue-type contact is so designed that there is no soldering or brazing used in its construction. A positive blade latch, which makes it impossible for the switch to be opened until tripped by the movement of the operating eye, is also incorporated. Tripping and opening are accomplished by a single downward pull with the switch hook. The blade consists of two copper channel-sections mounted back to back to form a narrow truss. On switches of 37,000 volts rating and above, the channel sections are formed in a wide truss which provides increased stiffness and mechanical strength. The standard switches are equipped with multi-bolt punched-tube terminals, with or without extended guide clamps.

## Portable Test Set

A portable truck-type high-voltage set for testing insulation and also transformer and circuit-breaker oil has been placed on the market by the Westinghouse Electric & Manufacturing Company. This set has a maximum testing voltage of 50,000 volts. The complete equipment consists of a testing transformer, auto-transformer, induction regulator, oil-testing cup and control equipment. The transformer of this set is of the oil-insulated, self-cooled, shell-type construction. One end of the high voltage winding is solidly grounded to the tank and the other is brought through the cover by means of a bushing. The auto-transformer adapts the set for the different primary voltage ratings. The induction regulator gives a variable, test voltage from zero to 50,000 volts in a continuous smooth curve. Red and green indicating lamps are provided, the green indicating voltage on the supply circuit terminals and the red showing potential on the high-tension terminals.

The control circuit consists of an overload relay with an electrical reset, a double-pole contactor with blowout coils and a make-and-break interlock for the signal lamps, all controlled from a pushbutton. A voltmeter coil is provided on the testing transformer, so designed as to develop a voltage equal to ½ per cent of the developed voltage. The terminals of this coil are brought out to suitable binding posts for voltmeter connection. As a further means of indicating test voltage a dial calibrated to the approximate high-tension voltage is provided on the tank cover with a pointer geared to the regulator shaft.

Motors for Use in Explosive Atmospheres—A line of both alternating- and direct-current motors, built for application where explosive gases, fumes or dust are present, is announced by the General Electric Company. These motors have been approved by the Underwriters' Laboratories for operation under such conditions. The announcement of the complete line marks the culmination of several years of application in individual sizes and rating. The motors bear the designation "Class BU Form JA" and are of a totally inclosed design.

# Electrical Patents

*Announced by U. S. Patent Office*

(Issued April 24, 1928)

1,667,638. Adjustable Magnet Device; H. B. Rex, Lynn, Mass. App. filed July 29, 1927. For controlling the effective flux of permanent magnetic damping devices such as those employed in integrating meters.

1,667,647. Electric Motor; E. F. W. Alexanderson, Schenectady, N. Y. App. filed March 11, 1925. Reversible motor wherein the same coils are utilized to produce both the exciting and commutating motor field fluxes.

1,667,650. Theft Signal Switch; J. P. Bradley and O. A. Prough, Weed, Calif. App. filed April 29, 1925.

1,667,652. Contact Finger; F. E. Case, Schenectady, N. Y. App. filed April 22, 1925. For drum controllers.

1,667,655. Controlling or Tripping Apparatus for Alternating-Current Electric Circuits; H. W. Clothier, Wallsend-on-Tyne, and W. A. A. Burgess, Monkseaton, England. App. filed Sept. 17, 1925.

1,667,656. Antitheft Attachment for Meters; W. A. Dilzell, New Orleans, La. App. filed Aug. 16, 1926.

1,667,660. Liquid Contact Connecter; E. H. Gehm, Stockton, Calif. App. filed Jan. 27, 1927.

1,667,662. Protective Arrangement; H. S. Holbrook, Rugby, England. App. filed Feb. 11, 1926. For the circuits of electric traction systems.

1,667,664. Compensated Induction Motor for Single or Polyphase Alternating Current; F. Kade, Kiel, Germany. App. filed June 20, 1925.

1,667,672. Frequency Changer; S. P. Nixdorff, Schenectady, N. Y. App. filed Sept. 22, 1926.

1,667,674. System of Distribution; O. Pollok, Berlin-Halensee, Germany. App. filed May 9, 1925. In which a mercury arc rectifier is employed in connection with translation devices capable of developing a counter electromotive force.

1,667,688. Clamp for Connection Boxes; W. Goetzelman, Chicago, Ill. App. filed Aug. 30, 1926.

1,667,702. Connecter; R. E. Powell, Toledo, Ohio. App. filed April 23, 1926. For storage battery.

1,667,704. Terminal for Storage Batteries; R. A. Szeits, Hawthorne, Calif. App. filed Sept. 14, 1926.

1,667,705. Self-Induction Coil; K. von Wysiecki, Lausanne, Switzerland. App. filed Nov. 28, 1925.

(Issued May 1, 1928)

16,947 (reissue). Motor-Control System; H. W. Williams, East Pittsburgh, Pa. App. filed Sept. 8, 1923. Employed in connection with elevators, machine tools and similar machines.

1,667,716. Key-Controlled Lighting and Ignition Switch; S. F. Briggs, Milwaukee, Wis. App. filed March 15, 1915.

1,667,718. Machine for Driving Nuts, Screws, and the Like; E. L. Connell, East Cleveland, Ohio. App. filed Dec. 11, 1925.

1,667,726. Electrical Hair-Curling Apparatus; C. Fayer, Flushing, N. Y. App. filed June 18, 1925.

1,667,743. Voltage-Gradient Regulator for High-Tension Cable Ends; E. G. Sievert and H. Svensson, Sundbyberg, near Stockholm, Sweden. App. filed Nov. 9, 1925.

1,667,746. Magnetic Alloy; W. S. Smith, Newton Poppleford, H. J. Garnett, Sevenoaks, and J. A. Holden, Gidea Park, England. App. filed Jan. 21, 1927. Magnetic substantially carbon free material comprising iron 10 to 17 per cent, silicon 1.5 to 4 per cent, a fourth metal selected from the group comprising chromium, tungsten, vanadium, and molybdenum 1 to 4 per cent and the balance nickel.

1,667,747. Relay for Electrical Control Apparatus; H. E. Somes, Philipse Manor, N. Y. App. filed Oct. 19, 1923.

1,667,752. Regulating Means for Systems of Electrical Distribution; P. H. Thomas, Upper Montclair, N. J. App. filed Aug. 27, 1924. A plan and a suitable apparatus for supplying electric power to local consumers from a high tension electric source and at the same time to supply power to or receive power from general distribution circuits connected at the same load point and to so regulate the relations of these elements as to preserve a suitable range of voltage and of current on each.

1,667,757. Light Signal; W. B. Wells, Wilkinsburg, Pa. App. filed Jan. 23, 1925. As used in railroad work.

1,667,758. Electric Boiler Apparatus; G. Welter, New Haven, Conn. App. filed June 28, 1926.

1,667,766. Magnetic Chuck; J. Bing, Eisenach, Germany. App. filed March 26, 1925.

1,667,775. Surgical Baker; W. S. Edmands, Boston, Mass. App. filed March 8, 1926.

1,667,794. Device for the Synchronization of Alternating-Current Machines; R. Michl, Kosice, Czechoslovakia. App. filed Jan. 10, 1924.

1,667,813. Outlet-Box-Supporting Means; J. Morgenstern, Cleveland, Ohio. App. filed Oct. 24, 1924.

1,667,814. Cable Clamp; J. Morgenstern and C. Raus, Cleveland, Ohio. App. filed March 17, 1926. For securing cables or conduits of electric wiring systems to receptacles such as switch boxes, outlet boxes, etc.

1,667,815. Electric Hot-Water Faucet and Means for Operating Same; A. M. Nickerson, Winthrop, Mass. App. filed May 10, 1926.

1,667,816. Electric Radiator; A. M. Nickerson, Winthrop, Mass. App. filed April 13, 1927.

1,667,817. Electrode; Y. Noishiki, Tokyo, Japan. App. filed Jan. 26, 1927. For electrotherapeutic application.

1,667,824. Multiple-Unit Cable; A. L. Richey, Boonton, N. J. App. filed Dec. 5, 1925.

1,667,828. Lamp Post; J. W. Speer, Lansing, Mich. App. filed Feb. 23, 1926.

1,667,857. Heating Unit; C. C. Harpster and W. R. King, Mansfield, Ohio. App. filed April 2, 1927. Incased tubular heating units.

1,667,871. Troughing System for Electric-Appliance Receiving Cabinets; J. Sachs, Hartford, Conn. App. filed Sept. 7, 1926. For meter service layout.

1,667,873. Disk-Pile Lightning Arrester; J. Slepian, Swissvale, and S. M. Pineles, Pittsburgh, Pa. App. filed Nov. 23, 1922.

1,667,879. Tubular Heater and Method of Making the Same; J. C. Woodson, Mansfield, Ohio. App. filed Sept. 2, 1926.

1,667,905. Electrical Measuring Instrument; J. Slepian, Swissvale, Pa. App. filed Dec. 15, 1924. For measuring the maximum value of an alternating voltage regardless of the wave form or frequency.

1,667,910. Lamp Grip; J. R. Townsend, South Bend, Ind. App. filed March 24, 1924. Retainers for electric lamps, fuse plugs and the like.

1,667,914. Pressure-Governed Circuit Controller; R. E. White, Chicago, Ill. App. filed Jan. 29, 1923.

1,667,954. Fluid Purifier; F. J. Simington, Chicago, Ill. App. filed July 12, 1926.

1,667,988. Automatic Electric Toaster; G. P. Richardson, Los Angeles, Calif. App. filed March 5, 1927.

1,668,016. Crystal Wire Filament for Incandescent Electric Lamps and the Method of Winding It; M. Hauschild, Dresden, and W. Berger, Blasewitz-Dresden, Germany. App. filed Feb. 23, 1926.

1,668,043. Extension Grip for Electric-Lamp Connecters; E. H. Bixby, Astoria, Ore. App. filed May 1, 1926.

1,668,049. De-electrolizer; M. A. Clinton and M. W. Collet, Philadelphia, Pa. App. filed May 20, 1922. Used to remove charges of static electricity.

1,668,106. Hot-Wire Vacuum Meter; W. Dällenbach, Zurich, Switzerland. App. filed May 12, 1924.

1,668,110. Electrical Transformer Construction; J. Fischer, Baden, Switzerland. App. filed Feb. 27, 1926. Tapping arrangements.

1,668,111. Terminal for Electrical Accessories; J. E. Gaffney, Birmingham, England. App. filed Dec. 16, 1924.

1,668,115. Magnetizable Material; E. Gumlich, Berlin-Charlottenburg, Germany. App. filed Nov. 30, 1926.

1,668,138. Fuse Plug; L. Baenziger, Abington, Mass. App. filed Feb. 23, 1927.

1,668,142. Heated Roller; J. D. Conger, Clarkston, Wash. App. filed March 7, 1927. Electrical combined, smoothing, heating and securing device for floor coverings, designed primarily for use in connection with linoleum.

1,668,161. Portable Electric-Control Apparatus; J. E. Long, Multnomah, Ore. App. filed April 13, 1927. For electric signs.

1,668,177. Alternating-Current Motors; H. Weichsel, St. Louis, Mo. App. filed April 4, 1925. Across-the-line type synchronous motor.

# New Trade Literature

MOTORS.—The Century Electric Company, 1806 Pine Street, St. Louis, is distributing a folder, form 663, describing and illustrating its most recent addition, the type DM direct-current motors.

POLE MOUNTS.—The Malleable Iron Fittings Company, Branford, Conn., is distributing a bulletin describing the "Williams" pole mounts for wood and tubular iron poles. Illustrations showing typical pole mount installations are included.

VACUUM-TUBE SYNCHRONIZING EQUIPMENT.—The General Electric Company, Schenectady, N. Y., has issued bulletin GEA-777A, covering its vacuum-tube synchronizing equipment, such as bushings equipped with capacitance transformers, outdoor amplifiers and indoor amplifier assembly, including motor-generator set and synchroscope. Illustrations and dimensions of the equipment are included.

SAFETY SWITCHES, POWER PANELS, ETC.—The Square D Company, Detroit, has issued catalog No. 33 covering its products, including safety switches, motor starters, power panels, porcelain insulators, "Square-Duct," test plugs and sockets, voltage testers, etc. Tables giving dimensions of switch boxes in inches and knockout sizes and locations and wiring data for motors are included.

INDUSTRIAL LIGHTING. — "Modern Retailing Success" is the title of booklet No. 444-A issued by the Holophane Company, 342 Madison Avenue, New York City. It contains an article entitled "Special Lighting," which features its control lenses for special lighting, and a number of illustrations showing various installations of Holophane reflector-refractors for show-window lighting, department stores, etc., are included. The company also is distributing booklet No. 600 covering lighting specifics for gasoline-filling stations which gives full information on Holophane units for the lighting of every part of the gasoline station and contains illustrations showing typical installations.

ELECTRICAL MEASURING INSTRUMENTS.—The Jewell Electrical Instrument Company, 1640 Walnut Street, Chicago, has issued catalog No. 16, covering the Jewell electrical measuring instruments. It describes and illustrates the various portable type instruments, switchboard and panel-mounting instruments and radio instruments. It also contains descriptions of its X-ray and electro-therapeutic and automotive testing instruments. The company also is distributing a circular which features its new line of "Master" portable instruments and its 7-in. line of switchboard instruments. The catalog is very complete and contains dimension diagrams and reproductions of the various scales employed.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered, further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number:

Purchase is desired in Wellington, New Zealand (No. 31,168), of small electrical devices.

An agency is desired in Dublin, Ireland (No. 31,112), for household electrical appliances.

Purchase is desired in Iquique, Chile (No. 31,109), of electric portable paint-spraying equipment for automobile bodies and metal work.

Purchase is desired in San Luis, Cuba (No. 31,111), of electric household refrigerators.

An agency is desired in Carmaux, France (No. 31,170), for sewing-machine motors.

Purchase and agency are desired Genoa, Italy (No. 31,128), for electrical machinery for ships and motor ships.

Purchase and agency are desired in Cardiff, Wales (No. 31,110), for electrical vibrators.

An agency is desired in Bietigheim, Germany (No. 31,127), for electrical washing machines.

# Business Facts for Electrical Men

Selected Statistics Presented Graphically for
the Use of All Interested in Analyzing the
Trend of the Electrical Business

## Water Power Serves Nation's Homes and Industries

THE preponderating percentage of energy generated from fuel in the more densely populated northeastern quarter of the United States and the predominance of water power in the far West and in the Southeast are evident from every fresh survey of our national electrical output. In the summary of operations of public utility plants for 1927, published in the ELECTRICAL WORLD of April 28, 1928, that situation again appears.

The hydro output amounted to 37.2 per cent of the total. More than half of it was reported from the Pacific and Middle Atlantic States. Water furnished more than nine-tenths of the energy in the Pacific States, not quite seven-eighths of that in the mountain region and almost two-thirds of that in the East South Central States. Even in these regions, liberally as they are endowed with water, reliance must nevertheless to some extent be put on fuel.

During 1927 the installed generator capacity increased by 2,292,506 kw. to a final total of 27,690,891 kw. The greatest increase in any one region, in rate as well as in amount, occurred in the South Atlantic States; the change from 2,835,074 to 3,475,795 kw. between the beginning and the end of the year exceeded 600,000 kw., or 22 per cent. Next came the Middle Atlantic and East North Central States. The West South Central region had the second highest rate, 19 per cent.

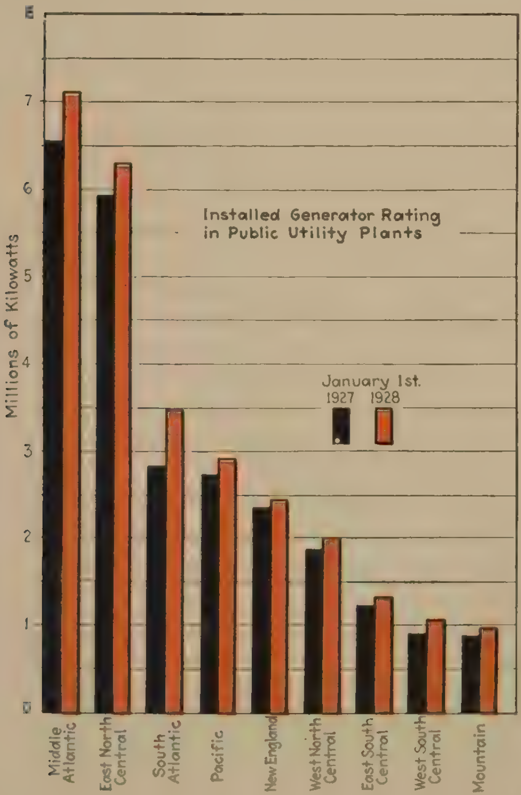
Most of the data for statistics in the ELECTRICAL WORLD are gathered by it from original sources. Privilege is freely given to readers to quote or use them for any legitimate purpose. While no acknowledgment is required, users will, by crediting the ELECTRICAL WORLD, help it in obtaining and compiling further basic information.

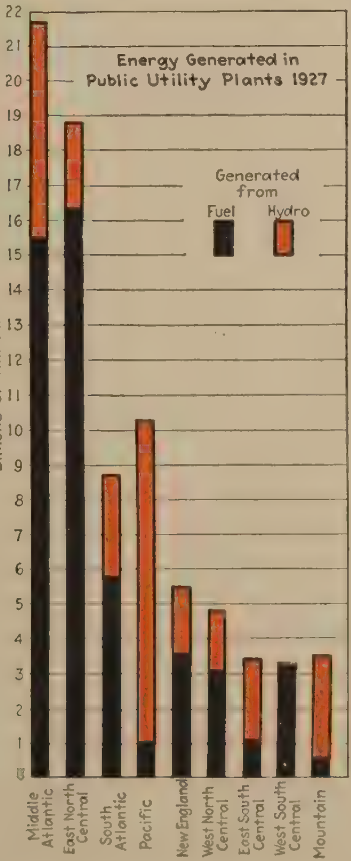
The Middle Atlantic, with 7,113,361 kw., and the East North Central, with 6,311,870 kw., continue to be the sections with the largest total rating, as might be expected in view of their rank in population and their industrial importance.

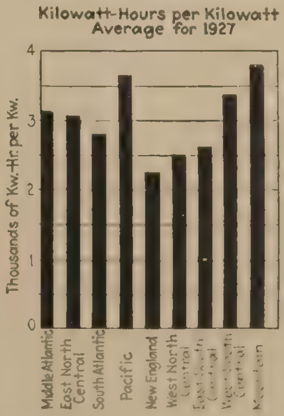
In kilowatt-hours per kilowatt, considering the latter as the mean of the installations at the beginning and end of the year, the two great water power regions stand out conspicuously. Both have large long-hour loads and the amount of steam reserve necessary is comparatively small. The Mountain States show the highest regional average, namely, 3,800 kw.-hr. per kilowatt. New England, where the lighting load is relatively large, fluctuates widely with the seasons, and therefore demands large peak-load capacity, and is at a definite disadvantage in this regard. No doubt the erection of new plants of high efficiency in the very recent past and the impossibility of at once eliminating the older plants have lowered the load factor in some regions, but this condition is probably to be regarded as temporary and unavoidable.

The national totals corresponding to these various regional figures are: 80,205,474,000 kw.-hr. generated in 1927; an installed rating of 25,398,385 kw. at the beginning of 1927 and 27,690,891 kw. at the beginning of 1928.

The data here quoted relate to all public utility plants in excess of 100 kw. and include not only those for light and power but also railway and other plants generating energy not exclusively for private use.







*Increase has occurred in every section. Output per kilowatt varies widely*

# Industrial Activity in the North Central States 5.7 per Cent Over 1927

MANUFACTURING plants in the North Central States have been reporting a rate of operations above that of the same month in the year previous ever since last October. The low point in activity reached during the winter of 1926 does not appear to have been duplicated during the past winter, due very largely to the fact that the production of equipment and replacement parts in the automobile industry was some 30 per cent above that of the winter of 1926, thereby raising the index of operations in that industry to a plane materially above that of the year previous. Since December the operations of industry in this section have followed very closely the trend established during 1927, but on a plane about 5 or 6 per cent above that of last year.

*Indexes of Productive Activity in the North Central States*

All Figures Adjusted for Number of Working Days

| | April, 1928 | March, 1928 | April, 1927 | Average for First Four Months, 1928 | Average for First Four Months, 1927 |
|---|---|---|---|---|---|
| All industries | 125.7 | 122.3 | 118.9 | 123.2 | 114.8 |
| Chemical and allied products | 146.2 | 129.7 | 97.4 | 113.5 | 94.2 |
| Textiles | 123.8 | 112.7 | 129.6 | 123.4 | 133.8 |
| Lumber and its products | 118.5 | 119.8 | 115.2 | 121.7 | 119.7 |
| Paper and pulp | 111.8 | 110.2 | 112.3 | 110.5 | 113.8 |
| Automobile, including the manufacture of parts | 148.7 | 136.0 | 138.3 | 142.3 | 109.5 |
| Rolling mills and steel plants | 129.9 | 127.5 | 129.5 | 131.2 | 125.6 |
| Metal-working plants | 133.3 | 130.0 | ..... | 131.1 | ..... |
| Food and kindred products | 108.7 | 115.2 | 108.2 | 111.5 | ..... |
| Leather and its products | 99.8 | 109.3 | 88.7 | 110.7 | ..... |
| Rubber and its products | 131.2 | 139.3 | 115.7 | 137.7 | ..... |
| Stone, clay and glass | 114.5 | 101.8 | 111.0 | 99.8 | ..... |

The rate of operations in April was about 2.8 per cent above March and 5.7 per cent above April last year. During the first four months of the current year the average rate of general productive operations in this section was about 7.4 per cent above that during the same period in 1927.

## *Stock Taking at Atlantic City Will Show No Cause for Alarm*

THE Atlantic City convention of the National Electric Light Association will be held under auspicious circumstances. Gratifying progress has been made by member companies of the organization, which means almost the entire electric light and power industry, and the only cloud discoverable in an otherwise clear sky is the investigation of the Federal Trade Commission. That, of course, involves only a small percentage of the membership of the N.E.L.A.; nevertheless, it will be difficult to get the public to believe that any policy of the few does not apply to all. The investigation is a challenge to the industry to enlarge and improve its public relations. What is being doled out by the sensational press makes its appeal to the heart, and if the heart governs the head, it is because not enough effort has been made to instruct the head.

Aside from the diversion which Congress and the Federal Trade Commission offer, the economic evolution of the business goes steadily on. Consolidations and mergers still occupy the attention of executives and bankers although playing havoc at times with operating organizations. It is inevitable that in the changes brought about in the interest of economy and better service some temporary maladjustments will occur; but so long as any human need or desire remains unsatisfied—and there is great demand for electricity—none in the industry need be without employment. Mergers are not to be feared. They are in keeping with the economic trend of the times. Properly conceived and executed, they make for stability, standardization of equipment and operating practices, simplicity of financial structure, greater opportunity for decentralized management with centralized credit and control, and cheaper and better service to the public.

Technically, the electric light and power companies, thanks to their array of outstanding engineers, have always made an excellent showing. If in anything they have not measured up to possibilities, it has been in commercial exploitation of their product. However, here, too, progress is beginning to be evident. Companies are adopting aggressive and balanced policies whereby new business is being sought and no longer waited for. Salesmen are out after new factories for their territory; surveys of resources are being made with a view of selling the region to national industrial groups; commercial and street lighting are being developed, and domestic load is taking on a new meaning. Only through the development of all classes of business is it possible to do pioneering in new business without jeopardy to the balance sheet, and it is gratifying to note that the electric light and power companies of the country, under the leadership of the national association, are beginning to visualize the opportunities of the business and to realize them commercially. Thus the industry bids fair to continue on its uninterrupted march of progress with satisfaction to itself and the public it serves.

* * * *

## *An Unfinished Industry*

DESPITE the epic proportions of the light and power industry it is unfinished. It has not yet attained the standards which all desire and which can be brought about. It will always be an unfinished industry, for the end of electrical developments is not even remotely visible and there is no boundary to the opportunities for service presented by the future. In this fact lies the inspiration for builders of the industry. The streams of electricity have entered into sixteen million American homes to afford light, to iron, to cook, to clean and to entertain. They have entered into cities and factories to give brain power unlimited possibilities to replace muscle power. They have flowed across natural resources and changed them into useful products for civilized man. It seems as if a modern Aladdin had indeed rubbed a lamp and sent warmth, light and energy into the world.

Our standards of living and comfort have risen through the progress of scientific research, discovery and invention and through our joyous application of every new development. New electrical devices fitted with the social instincts of our people and became the tools which helped to build national prosperity and comfort. In contrast as they are with past civilizations, our present standards are matters for country-wide gratitude to those who have guided electrical developments. They were men of large initiative and greater courage. But public gratitude must be earned through public understanding, and public understanding of the electrical industry does not exist in the degree necessary to enable it to do its best work.

The industry has grown too rapidly, it has expanded its services too greatly, it has invested money too heavily, and it has become too technical. In these respects it is far in advance of public understanding, and in this fact lies reason for serious thought. Those in the industry know that public good has been the inspiration for electrical developments. They know the joy which industry builders have experienced in developing every possibility for public service. They know that exploitation and enormous earnings have never characterized light and power enterprises. But people in general have not grasped utility values or utility ideals. They are apt to respond to demagogic appeals and to distrust corporations because of past experiences with large industries and because of innate prejudices against something big and not easily understandable.

These are matters which deserve the undivided attention of leaders of American thought. The initiative is with the electrical industry, but the responsibility is shared by all thoughtful leaders of industry in general. A growing and prosperous light and power industry is the greatest asset for maintaining and expanding nationwide standards of wellbeing. Whatever electricity has accomplished in the past is nothing when measured in terms of future possibilities. Builders of the industry have money, initiative and brains, but to use these tools to the best advantage they need public understanding as well. They and the public must belong to the same union and have, in addition, no jurisdictional fights. How to bring about this desired condition is the big problem confronting the light and power industry today.

* * * *

## *Tools for Doing the Job*

THE task of the electric light and power industry never changes and is never ended. Today as yesterday it is to provide good electric service at a fair price. It is to keep abreast of and apply technical progress in the art. It is to expand existing services and provide new services by acting upon all opportunities to bring savings and comforts into American homes and industries. It is to co-operate in all local, state and national activities which are worthy. It is to become a friend to its customers and remain one. It is to get public approval and understanding of its activities and policies. For the most part the light and power industry has succeeded in this work. Only in its attempts to get public understanding does there appear to be any degree of failure and a touch of the amateur. Human traits have not always been measured or appealed to intelligently.

A first reaction to the political hubbub at Washington is that the usual "public relations" practices should be discarded, forgotten and thrown away; that they have lost their vital significance and have become merely a departmentalized activity; that they strike false notes when they take the form of alleged propagandic pamphlets and books, of press releases which glorify and addresses which degenerate into self-eulogy, of professed altruism unsupported by acts, and even possibly now and then of political actions which call back to mind the railroad lobbyists of other days.

None the less, the tools used in the past to get public understanding are good tools if used properly. They should not be discarded. They should be sharpened and used more intelligently. The public utility information bureaus have done splendid work in making news available; books and pamphlets have been printed which are of great educational value; the light and power industry has leaders whose recorded addresses strike a very high note in announcements of policy and in contributions to American thought. The industry has a remarkably clean political record and has been noteworthy for its contributions to causes which sought to improve national welfare. Only in minor instances have the usual tools of the "public relations" department been used by clumsy hands. The point is, however, that these tools in themselves are unable to create public understanding and good will when wielded by a department only and when used in the customary manner. They must be supplemented by other tools.

Public relations must be part of the work of every utility man in all of his activities. An attractive-looking substation, a street without fairy draperies of poles and wires, a neatly uniformed employee, a truck driver who respects the rights of other motorists, a salesman who knows when to take "no" for an answer, a smiling employee at the complaint window, an executive group who are citizens, chamber of commerce men, clubmen and community builders because they like to be part of the community activities—these things gain and keep the confidence, sympathy and understanding of the community served. Utility advertising that supports community projects or that tells of actual contributions to community growth in a modest manner, utility show windows that tell the story of electric service in terms of tangible comforts made possible by appliances and set a pattern of style in display which other merchants desire to use, news releases which are free from bias and have human interest, addresses and talks to community groups about electricity and the local developments, commercial policies which bring co-operation instead of competition and, above all else, good service—all these tools are good and should be used intelligently by every utility.

Utility companies have no reason to be ashamed. There is no ignominy in fine service and no closet skeleton in their history. They are made up of people and are no more godlike than the people they serve, but there is an old proverb, "The servant of a king is a king."

* * * *

## *Engineers as Managers*

UTILITY engineers during the past year have been taking stock of their function in the light and power business. The result has been the development of some good plans and objectives. There is general agreement that engineers have a "dollar" responsibility in building systems and in addition that co-ordinated plans should replace current expedience in the development of a light and power property.

The assembly of an enormous amount of technical equipment is necessary in a modern plant. This equipment must operate to give service and, in this operation, must be controlled by engineers. In both assembly and operation the major function of the engineer, in the mind of the executive, is to get economic results. His technical competency is granted, but his business judgment has been challenged frequently. It is encouraging to note, therefore, that the engineer has come to realize his economic function, but he should go further and recognize his management function also, thereby introducing some human engineering into his technical plans and operations.

None is better equipped to manage utility properties than the engineer if he will add an understanding of men and an economic sense of values to his engineering qualifications. In a technical industry he has an asset which gives him the advantage over a lay competitor for executive position, but in the past the technical man has done very little to earn the executive standing for which he can qualify. He should plan economic systems and also manage them. The hired managers of the utility industry will be engineers, if the engineers will take the trouble to qualify for the posts.

## *Inducement Rates and Customer Revenue*

WHEREVER light and power companies have introduced inducement rates that enable domestic customers to use additional energy at low unit cost and have backed up these rates with vigorous sales effort they have raised considerably the average consumption per customer. Pittsburgh, without much electric range load, claims an average domestic consumption of 637 kilowatt-hours. Buffalo reports 743 kilowatt-hours. Out in the Northwest, with water heating added to range load, the average for most of the companies has gone away above these Eastern figures, and it reached 1,676 kilowatt-hours in the case of the Washington Water Power Company. Six Rocky Mountain and Pacific Coast companies averaged 502 kilowatt-hours.

Notwithstanding all these cases of high average consumption per domestic customer, however, the average annual domestic revenue ranges only from $25 to $33. As contributors to the general public in the form of more service for the same or little additional expenditure these companies have achieved results; but so far as regards making domestic customers more profitable not much progress has been made. Does this mean that the inducement rates are lower than necessary to attract business? Does it mean that the public sets a definite budget for electric service and will not spend any more? Or does it mean that enough additional household uses for electricity have not been found?

In any event the situation affords something to think about and act upon. Domestic customers individually and collectively have brought a notoriously low return for the investment to serve them, the cost of handling their accounts and the cost of maintaining service reliability. Certainly, the inducement-rate idea is not wrong—but added consumption should be profitable consumption.

* * * *

## *Mergers and Dividends Deserve Interpretation*

AN OPPORTUNITY exists for getting better public understanding of the larger business aspects of the public utility business. News of big mergers of operating and holding utilities or of stock dividend disbursements should include more than the bare financial details that are apt to suggest an atmosphere of "melon cutting" to the newspaper-reading public. There are tangible financial, operating and service reasons for mergers. All intelligent utility executives build their business on the basis of better public service as a fundamental, and they make business decisions as to mergers or dividends only after striking favorable balances in terms of benefits to the public as well as themselves.

The public has a right to know these reasons and needs them to understand the business moves. Private enterprise operates the majority of utilities in this country because it gives good service at a fair price. It acts as a hired executive, its books are open to public inspection, and there are many inducements that should lead utility executives to interpret their business transactions to the public they serve. Such a practice would prove good policy and good business, for it would gain the confidence of the public and thus help to police the industry. If the practice were universal, the exploiter and stock jobber would have no opportunity to exist because no legitimate reasons could be advanced for contemplated purchases or financing. The interpreted balance sheet so widely used by operating properties should be supplemented by a similar interpreted presentation of the tangible reasons for specific mergers and announcements of stock dividends or other operations of holding companies.

* * * *

## *Engineering Brains Needed for Building Business*

AN ANALYTICAL approach to the utility business calls for the type of training and approach typical of the engineer. The engineer has been very successful in the construction and operation of the physical facilities of the industry because he has planned his work in advance of installation and operation. Now the power industry is waiting with a new job for the engineer and it is of pressing importance. His orderly thinking is needed in the building of the market and in the commercial planning of utility expansion. For central-station selling has followed too long the easy policy of expediency and opportunism. The time has come when to the development of load should be given the same intelligent analysis and balanced effort that goes into the projecting and the designing and the progressive growth of a great transmission system. The same regard for the economics of the present and the future is called for both in the engineering and in the market-building enterprise.

All this would have been recognized long since had it not been for the fortunate popularity of electric service through the years. For a long time no selling was needed. Then it was but natural to seek the business easiest to secure. And the absence of commercial competition has ever been conducive to complacency. But now comes the commercial era. Systems will no longer grow by the simple accumulation of customers. New load must be developed in the years ahead by intensive selling—which raises two important questions: What kind of load and how?

The modern power company needs a fundamental development program if it is to answer these questions efficiently—a program that will govern the growth of the system in balance with the growth of the business. Based on the limits of the territory to be served, it should survey the prospective load and definitely plan the rate at which it shall be acquired. And this means a program for sales expense, a program for construction expenditure, a program for increase in operating costs—all advancing in step with a program for increased revenues expected and a clean-cut schedule of financial requirements.

In other words, a system plan for a modern utility is something more than a plan for the generation, transmission and distribution of energy, for the collection of bills and raising of money and for the maintenance of good public relations. The present-day power company is a great business. It needs commercial leadership and business judgment. It needs orderly market development, the kind that plans ahead what classes of load should be acquired for ten years and in what proportions. And this sort of selling can be as scientific a job as the building of a dam. It is high time, therefore, to apply more engineering brains to the building of the business of the power industry.

# Leaders in Home Service

### Pacific Northwest outstanding in domestic load building. 70,000 range customers contribute to high residential consumption. Railway electrification, hydro development and interconnection hold bright future

By WALTER C. HESTON
*Pacific Coast Editor*

*Chelan plant, Washington Water Power Company*

DEVELOPMENT of residential load is perhaps the outstanding accomplishment of the power companies of the Northwest, and having been leaders in this field they view with interest activities of utilities throughout the nation to get into tune with the commercial spirit of the day. Having an abundance of hydro-electric power, a limited industrial development and practically no unwired homes to which they might look for future growth, their efforts naturally have been directed to increasing consumption and revenue of existing domestic customers. Although the utilities of this section, which for the purpose of this article include the major utilities in the states of Oregon, Washington, Idaho, Montana and Wyoming, have been actively engaged in developing residential business for ten years or more, they are far from satisfied with results and are bending every effort further to increase residential consumption and revenue.

The electric range has been the chief contributing factor in this load-building program and the eight larger utilities of this section are now serving 70,226 range customers, bringing them an annual gross revenue of $2,809,000, or 26 per cent of the total revenue derived from domestic customers. Consumption of these ranges amounts to 34 per cent of the total energy sales to residential customers. New range users are being added at the rate of 17,500 a year, which means that 6 per cent of the available market is being sold each year, and there is every indication that this rate of sale will continue for several years. The largest number of range customers served by any one company is 22,369, on the system of the Puget Sound Power & Light Company. The Idaho Power Company has the greatest system saturation, with 31 per cent of its residential customers using electric ranges.

Taken in conjunction with water heating, the electric range has been responsible for very high average annual consumption per customer, reaching, in the case of the Washington Water Power Company, an average annual consumption for all domestic use in Spokane of 1,676 kw.-hr. The California-Oregon Power Company is a close second, with 1,423 kw.-hr. per year, and the Idaho Power Company is third, with 1,152 kw.-hr. per year. All companies show high averages, as will be seen from Table I. System data for eight major utilities are given in Table II.

Great possibilities lie in the development of the water-heating load also. The eight utilities referred to are serving 19,631 water heaters, which bring them a gross annual revenue estimated to be $900,000. These water heaters use annually 144,000,000 kw.-hr., which is 46 per cent of the total domestic energy sales of the companies concerned.

While intensive selling effort has been placed behind the electric range, and to some extent the electric water heater, increased use of lighting in the home and the

*Water power predominates in the transmission systems of the Pacific Northwest* sale of small appliances has not been overlooked. Some of the central stations in this group have done a particularly good selling job on small appliances, notably the Idaho Power Company, the Washington Water Power Company and the Pacific Power & Light Company.

What the future holds in the way of domestic use of electrical energy in this section is indicated in Figs. 1 and 2, which are curves projected to 1932 to show anticipated sales to residential customers in the city of Spokane. These may be considered typical for many of the other utilities. From this it will be seen that average use per domestic customer is expected to reach the figure of 2,560 kw.-hr. per year by 1932.

Attractive rates offered by power companies of the Northwest have enabled two transcontinental railroads to utilize central-station power delivered at high tension for electrification of their roads. The Chicago, Milwaukee & St. Paul has under electric operation its Cascade, Missoula and Rocky Mountain divisions, totaling 646 miles of main line and utilizing 40,000 kw. at an annual load factor of approximately 50 per cent. During 1926 the Great Northern placed 25 miles of its main line over the Cascade Mountains in western Washington under electric operation and before the end of the year expects to have 80 miles of its line between Skykomish and Wenatchee, Wash., electrified. This electrification will require approximately 15,000 kw. and is of special interest because of the fact that motor-generator type locomotives operating from an 11,000-volt, single-phase, 25-cycle contact line have been adopted.

With central station hydro-electric power available at reasonable rates throughout the Northwest and with increasing tonnage it seems reasonable to expect further electrification of these two roads and to look for the other two transcontinental lines serving this region to embark upon electrification programs.

Chief among the industries of the Northwest requiring large amounts of power are lumber, pulp and paper and mining. Of these the lumber industry utilizes the greatest amount of power, but is electrified to a lesser

---

# *Bright Outlook for Northwest*

*By Guy W. Talbot*
*President Pacific Power & Light Company*

BECAUSE industrial growth has been slow, the commercial departments of electric power companies in the Pacific Northwest have given their attention particularly to domestic load building. Here the increase in the use of electricity during the past few years has been most gratifying, in some districts the average number of kilowatt-hours used per residential customer having increased as much as 50 per cent. In fact, the average residential use in the Pacific Northwest is the highest in the United States.

The Pacific Northwest is latent with possibilities of industrial growth because of its great supply of raw materials and the large potential markets of the Orient. Greater industrial development, combined with the present large use of electricity in the home, will show a constant increase because of new uses, and greater extension of present uses, particularly in rural communities, makes it certain that this territory is destined to witness a most important development electrically. There is ample undeveloped power for future needs and there is an adequate developed supply for present needs and for the immediate future. Increased use of electricity, together with physical interconnections which serve to hold down fixed charges, will make for lower rates and, consequently, more universal use of electricity both in the home and in industry. These factors will contribute very materially to industrial progress through the use of power-driven machinery.

One of the big problems for the electric power industry, and all industries in the Pacific Northwest, and the entire country, for that matter, is to bring about a more equitable distribution of the burden of taxation, so that our public utilities, productive industries and agriculture may operate with greater economy. Real property and productive enterprises are bearing an altogether disproportionate burden of taxation. A pronounced impetus to industrial development in the Pacific Northwest can be occasioned by holding down taxation on productive effort and keeping government interferences in business at a minimum consistent with the necessary protection of the public from unfair practices and unnatural competition.

*Guy W. Talbot*

Taxes are not a controllable item, nor can we thwart costly and burdensome restrictions of government interference. These repressive factors can be kept within reasonable bounds only by an informed and rational public opinion. They are not alone our problems but those of all industries. Industry today is interdependent and must ultimately feel the effects of all political action directed against public utilities. Our tax burdens cannot be made lighter nor held within present bounds except by lessened expenditures in government. Only by avoiding unnecessary governmental ventures in and too many restrictions to business enterprises and by preventing obvious inefficiency and waste will economy in government be achieved.

degree than either of the others. Sawmills of Oregon, Washington and Idaho cut about 15,000,000,000 b.-ft. of lumber a year, requiring approximately 1,000,000 hp. Although as nearly as can be estimated only 10 per cent of the mills are motorized, electrically operated mills have installed 500,000 hp. in motors and are responsible for 50 per cent of the total lumber production. For the most part mills produce their own electric power from steam plants burning mill refuse. Of the 375,000,000 kw.-hr. per year utilized in electrically operated mills not more than 5 per cent is supplied by central stations. The reason for this is quite apparent. The mills fall into three general classes, those that are so remote from power transmission systems as to make the cost of extending lines prohibitive, those that are within reach of central-station power but still feel that it is more economical to generate their own power and those that have found some means of disposing of their waste and purchase central-station power. Thus it is largely a case of the cost of extending transmission lines or disposing of waste at a price that makes it economical for the mill operator to purchase power. For the most part sale of mill refuse has been limited to power companies and small industrial concerns for use under boilers in steam plants. Success with stoker firing of mill refuse in household furnaces and the development of processes for utilizing sawdust and "hog" fuel in the manufacture of pulp and wall boards is offering the mills a further means of disposal and the central stations an ever-increasing market for power.

†Derived by deducting 6,000 kw.-hr. per year from total residential sales for each water heater served and dividing by the number of residential customers.

The pulp and paper industry is rapidly coming to the front in the Pacific Northwest as Eastern sources of pulp wood are being depleted. At present there are 22 pulp and paper mills operating in Oregon and Washington, six of which are in Oregon and the balance in Washington. The daily output of these mills in paper products, such as newsprint, wrapping, writing, book, board and all other papers, is approximately 2,020 tons of finished product, for which the pulp requirements consist of sulphide, sulphate and soda pulp and total around 2,200 tons. In addition, two new mills are now building in Washington which will produce 270 tons of pulp daily and additions in an Oregon mill will add a production of 120 tons of newsprint daily. Newsprint production is the largest and as of the first of this year amounted to 1,077 tons per day for all mills. Other production was: Wrapping paper, 470 tons; writing and book paper, 125 tons; board, 220 tons, and tissues, fruit wraps and all others, 120 tons, daily.

From a power standpoint the 22 mills represent a total connected load of 136,827 hp., with an average power demand of 67,425 hp., a large percentage of which is central-station power. A few mills generate a small part of their power requirements either in hydro or steam stations, the steam being utilized in various processes after passing through the turbines.

*Spokane only.

The paper industry as it has developed in the Northwest exceeds by far the lumber industry with respect to the class of plants built, engineering involved, high-grade equipment used and the large amount of electrical engineering involved, particularly if the plant is for manufacturing newsprint.

Until quite recently paper produced by the mills on the Coast and British Columbia was used to supply the Coast trade. Recently, however, certain of the plants have been shipping bleached sulphide pulp to the East Coast, competing with similar pulp coming into the east from Canada and abroad. Due to the low freight rates applying on material of this kind from the Pacific Coast to the Atlantic seaboard, it is said that it is possible to deliver pulp to New York or other Eastern seaports as cheaply as from the mills in Michigan, Wisconsin and Canadian points as well as pulp imported from Norway, Sweden and other foreign countries. With the vast undeveloped timber and hydro-electric resources of the Northwest the outlook for the pulp and paper industry is promising indeed.

There are two important mining regions in the territory under discussion. In the Cœur d'Alene district in Idaho there are extensive mining operations producing chiefly lead, zinc and silver; at Butte, Mont., is one of the largest and richest copper deposits in America.

These mining operations are all extensively electrified and central-station energy is used in all cases. At the Butte mines of the Anaconda Copper Mining Company 27,000 kw. is utilized at an annual load factor of approximately 80 per cent. At the Great Falls reduction department of the same company the load is approximately 65,000 kw., of which 50,000 kw. is utilized at an annual load factor of 95 per cent in an electrolytic zinc plant. This plant requires 1.73 kw.-hr. per pound of zinc produced and has an output of 335 tons of pure zinc each 24 hours. A plant of similar capacity is now nearing completion at Anaconda which will be operated by the same company.

At Kellogg, Idaho, the Sullivan Mining Company will place in operation in June a 50-70-ton electrolytic zinc plant which will utilize 8,000 kw. of central station energy.

The importance of the mining load to the Montana Power Company and its effect upon system load factor may be judged from the fact that 83 per cent of the energy sales of this company are made to mining properties. The annual system load factor is 81.5 per cent.

Data on system growth for the eight large Northwest power systems used as an index to show major trends are given in Table III. It will be seen that for the systems of the California Oregon Power Company, Pacific Power & Light Company, Northwestern Electric Company, Portland Electric Power Company, Puget Sound Power & Light Company, Washington Water Power Company, Idaho Power Company and Montana Power Company, which produce 82 per cent of the energy sold in the Northwestern states, 68,000 kw. of additional generating capacity is required each year based on the growth during the past five years. These combined systems, which are showing an over-all annual increase of approximately 20 per cent in energy produced, require $16,000,000 of new capital each year.

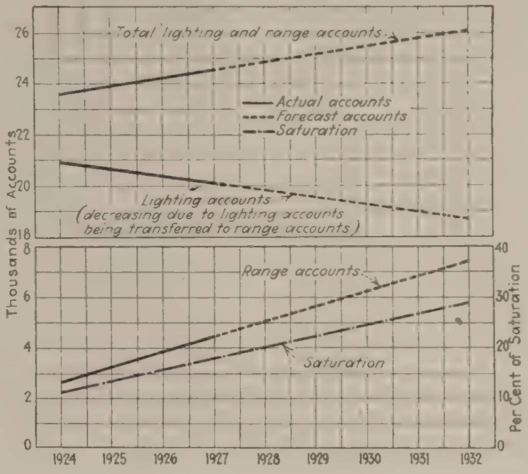

*Fig. 2—Forecast of electric range business in city of Spokane*

The greatest individual system growth has been that of the California Oregon Power Company. This company has more than trebled its installed plant capacity and has practically trebled its output in the past five

*Puget Sound Power & Light Company, Montana Power Company, Portland Electric Power Company, Washington Water Power Company, Pacific Power & Light Company, Idaho Power Company, Northwestern Electric Company and California Oregon Power Company.

years. This has been due largely to wholesaling large blocks of power to the Mountain States Power Company on the north and to the Pacific Gas & Electric Company on the south.

Four of the eight major utilities of the Pacific Northwest are strictly hydro-electric companies and of the remaining four only 29 per cent of their capacity and 14 per cent of their generation are from steam. Taking the eight properties as a whole, steam plants constitute only 12.5 per cent of the total plant capacity and produce only 5.2 per cent of the kilowatt-hours generated. This condition has been brought about by the utilization of numerous small hydro-electric sites within short transmission distance from load centers and capable of low cost development. The potential water power capacity of Oregon, Washington, Idaho, Montana and Wyoming is given by the U. S. Geological Survey as 13,531,000 hp., of which 1,898,705 hp. had been developed up to the close of 1927.

### Formerly Uneconomical Developments Becoming Economical

To one who views the situation from the outside it appears that power development in the Northwest is to undergo a radical change during the next five to ten years. Since a large part of the smaller economical sites have already been developed it will be necessary to look to the larger potential water powers, development of which has been uneconomical due to the fact that the rate of growth of any one or two systems has been insufficient to absorb a large block of power in a reasonable period of time. All of the eight systems mentioned, with the exception of the Idaho Power Company, are interconnected, but the ties are of relatively small capacity and not at all adequate to permit distribution of a large block of power which might be developed on the Deschutes or Columbia River to the important load centers.

With four of the eight utilities now under the same holding company management it would appear that development of the 260,000-hp. Kettle Falls site on the Columbia River or the 350,000-hp. Priest Rapids site on the same river and the transmission of this power over 220-kv. trunk transmission lines to the load centers of Puget Sound, Portland and Spokane is imminent. From Kettle Falls to Spokane is approximately 90 miles; to Seattle, 225 miles, and to Portland, 350 miles. Priest Rapids is almost equidistant from the three cities, the distances being approximately as follows: To Spokane, 150 miles; to Seattle, 150 miles, and to Portland, 175 miles. With the existing transmission network of the Northwest as indicated on the accompanying map and properly placed 220-kv. trunk lines it would be a simple matter to provide for a free flow of power from either of the above sites or any of several others to the power markets of the Northwest. Stream flow east of the Cascades is almost diametrically opposite to that west of the Cascades and the situation is ideal for development of one of the larger power sites in central Washington or Oregon as the next major step in expansion of Northwest power systems.

# *More Service at Reduced Cost*

*By Franklin T. Griffith*
*President Portland Electric Power Company*

*Franklin T. Griffith*

IN practically every state in the Union the control of electric rates is vested in public service commissions. The fundamental principle of regulation is that the serving company is entitled to such rates as will permit it to earn the cost of operation, taxes and a reasonable return upon the value of the property devoted to public service. There is no guarantee that the utility shall earn such return, but there is, under regulation, ample protection against the establishment of extortionate rates that would produce more than a reasonable return on the investment.

The average cost to the consumer of electrical energy throughout the country, and particularly in the Northwest section, is lower now than at any time in history. This has been brought about by increasing the efficiency of operation and increasing the use of energy by consumers.

All rate schedules are designed to lower the average cost per kilowatt-hour as the consumption increases, so that today the average cost per kilowatt-hour served to the residences of Portland, for instance, is less than one-half of the average cost per kilowatt-hour ten years ago. There is every reason to believe that as use per customer increases, as it certainly will, the cost per kilowatt-hour of energy delivered will continue to decrease.

If the Federal Trade Commission, or any other fair-minded investigating body, investigates the rate structures of the utilities now serving electric needs in the Northwest, I am quite sure it will be found that the principle of regulation above referred to has been rigidly adhered to.

# Public Understanding

## Should Not Fall Behind Industry Growth

By H. T. Sands

*President National Electric Light Association*

NOT only are the electric light and power companies of the country constantly striving for higher standards of public service but they realize how essential it is that public understanding of these utilities should not fall too far behind the growth of the industry.

The twelve-month period being brought to a close with the fifty-first convention of the National Electric Light Association has shown the industry to be increasing its contributions to the social and economic life of the country.

The household consumption curve is steadily rising. It is estimated that the average home in the United States consumed 5 per cent more electricity in 1927 than in 1926, and for this same period the average household bill for electric light and power increased only about 2 per cent. During 1927 the average cost per kilowatt-hour for domestic consumers decreased from 7 cents to 6¾ cents. This is incontrovertible evidence of the caliber of the service that the electric companies are giving to the country. These trends toward improved service and lower rates are continuing and it is apparent that the domestic load will become heavier as widespread appreciation of home electrification is fostered by electric light and power companies, manufacturers, contractors, jobbers and dealers.

The amount of electricity employed in industry is dependent on industrial activity. This showed a diminution in some parts of the country for the first months of 1928, but manufacturing is now consuming more power in many sections. Not only is industry relying more each year on the power facilities of electric light and power companies but the rapid development of interconnection gives ample supplies of current. Not only are smaller cities attractive to industrial activities but other decided advantages of interconnection are reliability and economy. It was the interconnection of the private companies that saved the city of Los Angeles from being without light and power when the St. Francis dam collapsed.

The completion of the Great Northern project adds another unit to the electrified railroad lines, the huge sums of money involved in this work naturally retard rapid advancement, but the advantages of electric trains in some centers and along some lines are overweighing the difficulties involved. The electric light and power companies, also, are persistently pushing farm electrification and rendering to the rural sections the same advantages that are at the disposal of all city dwellers.

The industry has been busy and it sees, and all the members of this association see, that it will continue to be busy.

# Serving Diversified Industry

### Ohio, Indiana, Illinois, Michigan and Kentucky record notable utility progress. Dense populations and diversified industries require high service standards

By T. P. KINDIG
*Western Editor*

ELECTRIC utilities located in the East Central States of Ohio, Indiana, Illinois, Michigan and Kentucky have been confronted by no mean array of problems in developing and building their systems to supply an electric service that must at once meet exacting requirements in dependability and adequacy and be economically profitable from an investment and operating standpoint. In these five states slightly more than 20 per cent of the entire population of the United States is concentrated. The territory itself presents a wide variety of characteristics in that it contains a number of cities of metropolitan proportions, it is highly industrialized, agriculture is carried on extensively, mining and the production of raw materials are of great importance. A glance at the industries and resources of each state will show considerable diversity of business but nevertheless reasons for mutuality of interest between states.

### CHARACTER OF TERRITORY

Ohio's leading industry, the manufacture of iron and steel, covers the entire northern and eastern part of the state along Lake Erie and down toward Pittsburgh. This state stands first in the output of pottery, machine tools and rubber goods and ranks second in automobiles and electrical machinery. Agriculturally it ranks fourth in the value of crops.

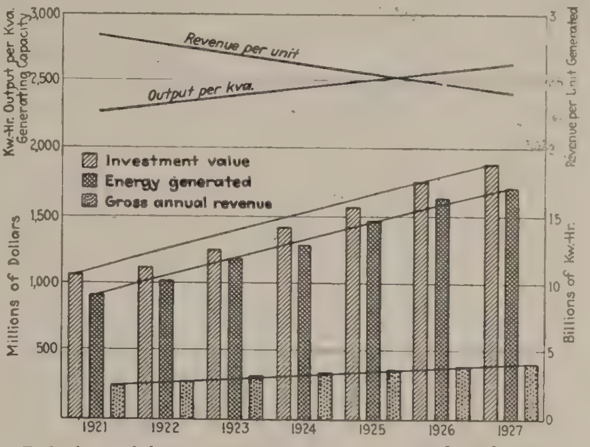
Indiana also has a large share in the production of iron and steel. It produces 70 per cent of the limestone used in the country for building and is a large producer of coal, petroleum, natural gas, pottery and cement. Almost the entire state is farmed intensively.

Illinois boasts of the second largest city in the United States. It stands first in the manufacture of meat products, agricultural implements and railroad cars. In value of farm products it ranks third and is one of the leading producers of coal and petroleum.

Michigan's production of automobiles is more than equal to the value of the automobiles produced in the rest of the country. It is the center of the country's furniture industry. Diversified farming gives the state a high rank in the total value of its crops and it is an important producer of iron ore, copper and coal.

Kentucky, long known as a great producer of tobacco, is rapidly taking on a distinctly industrial aspect. The state is a large producer of coal and its iron and steel industry is growing rapidly. It is an important railroad gateway for traffic from the South, West and North and a large amount of building material is produced in and shipped out of the state.

These five states have been the field of a vast commercial and industrial development during the past ten years. The central-station companies in this area have not only kept abreast of these developments but anticipated future requirements, fostered industrial and commercial development and extended their service as rapidly as practicable to the uttermost limits of the territory. How well they have done this and the consequent benefit to the public is told, in part at least, by the accompanying maps, graphs and tabulations.



*Relation of investment, energy generated and gross annual revenue*

In the upper diagram it will be seen that the energy output per kilovolt-ampere of generating capacity has increased about 15.5 per cent in the past six years, indicating improved operating efficiency. At the same time the gross revenue received per unit generated has decreased 14.7 per cent, showing that the major portion of the economy has been passed on to the public.

### SIX YEARS' PROGRESS

From 1921 to the end of 1927 the central-station companies added $830,789,700 to the investment value of their properties, an increase of 68 per cent. Generating capacity increased 79 per cent, to 6,645,000 kva.; number of customers grew to 5,084,200, or 78 per cent; gross revenue was raised 71 per cent, to $416,968,500; miles of transmission lines rose to 27,900, or 53 per cent; energy generated increased 101 per cent, to 17,285,000,000 kw.-hr.; population grew only 12 per cent, to 24,184,000, and the per capita production of electric energy rose from 395 to 715 kw.-hr. per year, or 85 per cent.

While the output per unit of generating capacity has been increasing, denoting better efficiency and more economical operation of power plants, the gross revenue received by the utilities per unit of energy generated has decreased 14.7 per cent in six years. In other words,

*Transmission system of the largest power pool in the Middle West, showing principal power companies' territories*

the results of more efficient utility operation and larger customer consumption have been passed on to the public in the form of lower rates.

The principal load centers are in the large cities, which have grown to their present size because of certain natural resources or their adaptability to commerce. They are situated chiefly on the Great Lakes and the Ohio and Mississippi Rivers. These waterways have also provided the essential sites for electric generating stations. Electric power at low cost has been a considerable factor in furthering the industrial growth of these cities.

In recent years there has been a marked tendency on the part of manufacturing industries to locate their plants away from the large centers of population. This trend toward decentralization would have been greatly retarded, if not made wholly impossible, were it not for the fact that large blocks of electric power could be obtained from high-tension transmission lines of the utilities at points considerably distant from the metropolitan areas. Still another factor influencing utility development in the East Central States is the large number of small cities and towns which have grown up as local commercial centers of agricultural activity with comparatively little manufacturing interest. Most of the cities and towns of this size had electric service of a sort, supplied from inefficient local plants, sometimes municipally and sometimes privately operated, with little hope of improved service because of lack of capital, incentive and vision of future possibilities.

With these elements the electric utilities have been and are confronted with the following conditions of service requirements: (1) Large metropolitan centers combined with intensive local industrial areas; (2) medium-sized cities with increasingly important but less intense industrial activity; (3) small non-industrial towns which merge into and carry with them the problems of rural service.

The accompanying map, which shows some of the most important power stations and the network of transmission lines, tells better than words how the utilities have gone about meeting power requirements.

*Total Number of Customers by States—Dec. 31, 1921, to 1927*

| | 1921 | 1927 |
|---|---|---|
| **Ohio** (total) | 708,500 | 1,447,000 |
| Domestic | | 1,228,000 |

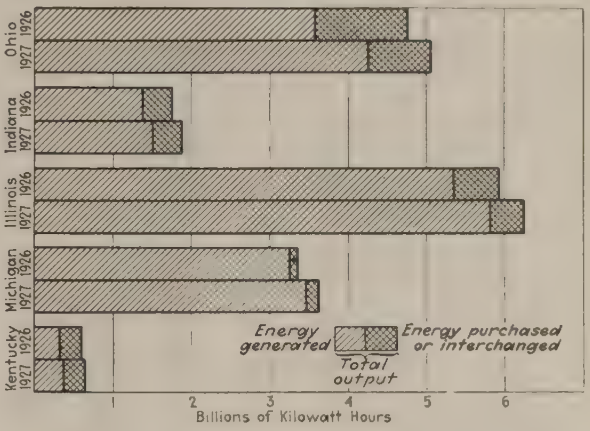
| Domestic | | 4,252,440 |
| Commercial | | 660,290 |
| Power | | 171,470 |

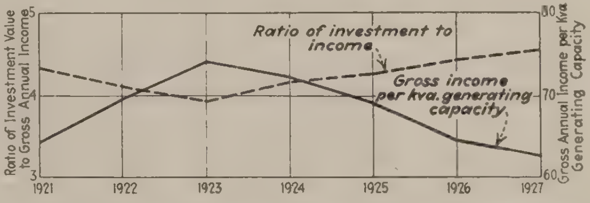
They have developed along several different lines: First, there is the power pool, where a number of large generating stations are located in and about the heaviest load centers. These stations are linked together with heavy tie lines and provision made for interconnection with other systems. Second, there is the territory where load concentration is not so heavy and generating stations are located advantageously for condensing water and coal supply, with radial or loop lines supplying the intervening territory and connecting with other systems. The third system plan also provides for advantageous location of generating plants, but because of the rather widely scattered nature of its territory considerable provision is made for interconnection and interchange of power with other utilities. A fourth general system is found in those territories which cover a wide area and whose power supply comes from hydro-electric plants and interconnection with other systems. Such systems employ longer transmission lines and as a general thing industrial loads are not as highly concentrated. There are, of course, many modifications of these classifications and some systems embody some of the elements of all.

### TYPICAL SYSTEMS

Typical of the first general plan are the Commonwealth Edison Company and the Public Service of Northern Illinois, which form the principal elements of the Chicago power pool. The Detroit Edison Company represents, in a single utility, the development of a power system to serve an intensely industrialized metropolitan district. The Cleveland Electric Illuminating Company, the Columbia Gas & Electric Company of Cincinnati and the Louisville Gas & Electric Company also represent this type of system in somewhat modified degrees. The second type of system is illustrated by the Penn-Ohio Power & Light Company at Youngstown, Ohio; the Illinois Power & Light Corporation and the Central Indiana Power Company. The Ohio Power Company, the Ohio Public Service Company, the Central Illinois Public Service Company and the Interstate Public Service Company in Indiana represent the third classification. Typical of the fourth general system plan are the Consumers Power Company in Michigan and the Kentucky Utilities Company.



*Total output and interchanged energy, 1926 and 1927*



*Ratio of invested dollars to gross annual income has increased, while gross income per kilovolt-ampere of generating capacity has decreased*

Central-station companies in the East Central States have been noted for pioneer engineering in adopting such things as pulverized fuel, high-pressure boilers and

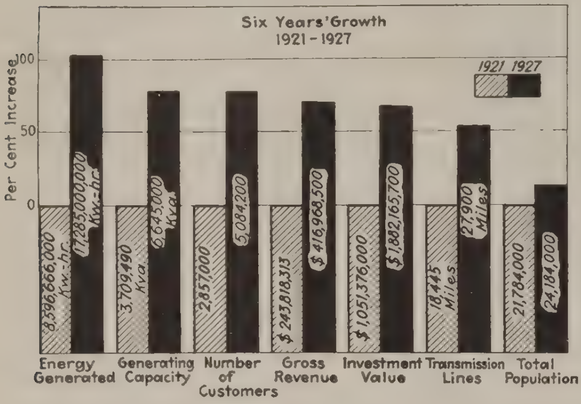
turbines, large single-shaft generating units and base-load plants. They have also been consistent in producing energy at maximum economy. The Columbia plant of the Columbia Gas & Electric Company holds the record for thermal economy in B.t.u. per kilowatt-hour.

### ADDED GENERATING CAPACITY

As a further example of this tendency to undertake large scale operations which reduce production costs and improve service to the public the project for the State Line Generating Company may be cited. The first unit of this plant is now under way on the shore of Lake Michigan on the Indiana side of the Illinois-Indiana state line. This project contemplates the generation and sale of power to several Illinois and Indiana companies whose transmission lines have been brought to a common focus at that point. The proposed ultimate capacity of this plant is 1,000,000 kw. and the first unit will produce more than 200,000 kw.



*Six years' growth of electric utilities in five states*

Many additions to generating plant capacity are under way through the territory. The Detroit Edison Company is going ahead with the construction of its Delray No. 3 plant, the first unit of which will be 100,000 kw., and is installing the sixth 50,000-kw. unit at Trenton Channel. The Cleveland Electric Illuminating Company is adding the third 35,000-kw. unit at Avon. At Philo station of the Ohio Power Company 165,000 kw. is going in, while the Ohio River Edison Company is installing 37,500 kw. at Toronto. The Columbia Gas & Electric Company is increasing the capacity of its system by some 100,000 kw. by additions to its Columbia, West End and Millers Ford stations. The Louisville Gas & Electric Company added 80,000 kw. of hydro-electric capacity this spring when the Ohio Falls plant went into operation. A 104,000-kw. unit is going into the Crawford Avenue station of the Commonwealth Edison Company. A new plant, the first unit of which is 50,000 kw., is being constructed at Pekin, Ill., to supply the increasing demand for power in central Illinois. These are only a few of the additions being made to generating capacity, but they serve to show how the electric utilities in the East Central States are preparing in advance to meet the increasing demand for electric energy.

### TRANSMISSION NETWORKS

The extent of transmission lines and interconnection is fairly well indicated by the map of the area. In general, the lines radiate from the heaviest load centers—Chicago, Cleveland, Detroit, Toledo, Cincinnati, Louisville and those plants on the Ohio River and in eastern Ohio. They extend from Chicago to the Mississippi River at Keokuk and to the southwest connecting with St. Louis and also cross the heart of the Illinois coal fields. To the south the lines reach the southern limits of the state and will shortly be connected with the systems across the Ohio River in Kentucky. Interconnected systems link Illinois with Indiana at several points, and extend across the Ohio River at Louisville, tapping the water powers in Kentucky. Within the state of Indiana is a series of interconnected systems, some of which form loops and others direct lines almost across the entire state. These lines, in turn, are interconnected with the systems in Ohio. Kentucky, as just noted, feeds power northward into Indiana and is rapidly completing a transmission system which will tie together the two great coal fields in the southeastern and southwestern parts of the state. From Louisville lines extend south, east and north.

In Ohio there is one unbroken line extending across the state from the southwest to the northwest and into Indiana. From Cincinnati lines extend in every direction and directly across the state. The northwestern section is covered by one of the most highly interconnected transmission networks in the country. It is now connected with Toledo, from where lines extend into southwestern Michigan and westward to Indiana.

In Michigan there is the Consumers Power Company system, which in itself represents a great interconnection of transmission lines, hydro and steam plants. This system is now tied in with Detroit, from where lines extend into the thumb of the lower peninsula of the state.

# Domestic Load Development

*By Alex Dow*
*President Detroit Edison Company*

*Alex Dow*

ON THE assumption that there will be an average annual use of not less than 1,300 kw.-hr. per domestic customer, the Detroit Edison Company now has in progress the rearrangement and reconstruction of its secondary circuits in the residential districts. This rearrangement is, of course, a slow job. It begins where it is likely to be most needed and it will be two or two and one-half years in extending to the lines where there is at the present time a comfortable excess capacity above the recent use of about 560 kw.-hr. per average customer.

To develop domestic load good service, particularly maintenance of voltage, is a *sine qua non*. A reasonable rate schedule is another. A schedule which, regardless of its make-up in the earlier billing blocks, will offer a sharp reduction in the rate for supply above the present average is desirable, and is successful in places where it is already adopted. A last condition, which is not so well understood as it ought to be, is provision for quick servicing and cheap replacements of domestic appliances. If the makers of range-heating elements, for instance, could get together and standardize on their sizes and connections it would be a big help to sales.

---

Lines also extend into the southwestern part of the state from Indiana and other interconnections are under contemplation.

While some of these interconnections are suitable only for local interchange of power, there is a very definite tendency toward increasing the capacity of these tie-ins and the revamping of lines to transmit larger blocks of power.

While the work of tying separate systems together is going ahead, it is interesting and significant to note how much energy is exchanged between systems. A comparison has been made of the total amount of electric power interchanged by the utilities in the five states in the years 1926 and 1927. In 1926 2,463,527,162 kw.-hr., or 15.1 per cent of the total output, was either purchased from or exchanged with other utilities, but in 1927, while the total output increased, the interchanged energy amounted to only 1,847,000,000 kw.-hr., or 10.7 per cent. This does not mean that the interconnection of systems is any less important, but rather that systems formerly purchasing a considerable part of their power have found it economical to increase their own generating capacity. Also, some companies formerly operated separately and which purchased power have been consolidated or merged with the supplying company and the power transmitted is now reported as the total output of

*Four 66-kv. circuits from the Columbia terminal of the Columbia Gas & Electric System* one system. Interconnection has therefore been the means of pointing the way to the most economical method of serving a given territory from the system of a single well-organized and operated utility.

### COMMERCIAL DEVELOPMENT

Commercially, the central-station companies in the East Central States have expanded just as rapidly as they have physically. Few companies in 1921 had well-organized new-business departments. As a result of the war and post-war conditions the utilities' commercial departments were reduced in personnel and for the most part were working with skeleton organizations. It has been necessary, therefore, virtually to create entirely new sales staffs, map out and carry through sales programs and redevelop the central-station sales technique. That this has been done well and efficiently may be seen by comparison of a few significant figures for 1921 and 1927. The total number of customers has been increased by 2,227,200 from 2,857,000 in 1921. Total kilowatt-hour sales have more than doubled, and while the population of the area has increased by about 12 per cent the use of electric energy per inhabitant has grown from 395 kw.-hr. to 715 kw.-hr. per year.

From an industrial power standpoint utility commercial departments have worked closely with the manufacturers in their territories. Electrification of industry has gone ahead rapidly with the aid of the central-station power sales engineers and the trend toward decentralization of industry, previously mentioned, must be credited largely to the extension of reliable utility service into nearly all parts of the east central area. This trend has gone hand in hand with the commercial and physical development of the power companies.

### CUSTOMER OWNERSHIP AND PUBLIC RELATIONS

While the central-station industry has been expanding its systems and service, at the same time it has not over-

*T. O. Kennedy*

"DON'T give her a book for Christmas; she has a book." This is an old joke, but immortal because it has much wisdom in it. Apparently we electric utility executives, as a class, have never seen the point of that merry jape. If it were plain to us we would long ago have seen its obvious parallel in our industry.

"Why try to sell electric service to the people of the United States? They already have electric service."

There is hope that the point will finally become clear. It ought to because a lot of men are trying to explain it with charts, curves, diagrams and geysers of words, accompanied by much appropriate gesticulation. All are saying that just as the possession of one book does not prevent the enjoyment of many more books, so the fact that electric service is in the home does not prevent its extension to many more profitable uses.

Compared with other nations, our country is the leader in electrification progress, industrial, commercial and domestic. Our arms have developed swivel joints from patting ourselves on the back, but at the same time we calmly admit that one-third of our total business is unprofitable and we refuse to let it bother us, much less do we take effective action to correct the condition.

We are agreed that the residence business on our lines as a whole is hardly more than paying its way—if it is doing that. We are agreed that this business can be made to pay an adequate return, a return that will be open to no criticism because it will be accompanied by lower rates and greater service to the users of energy. We have the necessary equipment, devices and appliances already developed and of proved ability to build up the residential load. All we have to do is to get these energy-consuming devices on our lines by selling, either selling them ourselves or by encouraging others to sell.

The essential thing is not the manner in which appliances are put on the lines; it is to get them there. In the small progress already made by the commercial spirit in the electric utility industry the end has always been obscured by the means; among all the trees we have lost sight of the forest. In talking and worrying about how the job should be done we have forgotten the job itself.

The commercial development of our business in the widest field of electricity application, the home, has not got over the first hurdle in the race. That hurdle is executive interest. Not the interest that expresses itself in a mild, "Yes, yes, that's right. We ought to do something about that some time," but an active interest that manifests itself in enthusiasm, in an appreciation, not only of the size of the job but of the reward to follow its completion, and in participation in the work.

The electric utility industry is more than forty years old. It is commonly referred to as being still in its infancy, but with a brilliant future. This must be true because in one regard at least, domestic service, it is a terribly backward child.

It is time that the utility executive, the daddy of the electrical industry, took a more active interest in the rearing of his child.

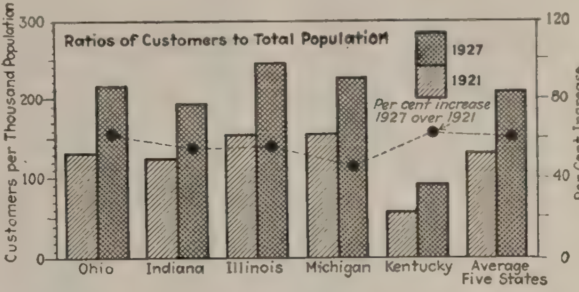
looked the value of taking its customers and employees into partnership through the sale of preferred stock, and there is scarcely a company which cannot boast of the fact that a large per cent of its customers are also stockholders. Many companies have established a fixed policy, when new capital is required, of obtaining part or all by the sale of its preferred stock direct to customers. So well has this practice been received by the public that frequently the stock issue is far oversubscribed within a few days after its first offering. Such an attitude on the part of the public speaks volumes for the cordial relations between the utilities and their customers and belies any alleged need for an investigation of the practices of these utilities.

In the construction of additional transmission systems and generating stations, work is going ahead in an orderly manner. There is still some work to be done in allocating certain territories and districts to those companies best situated to provide service. This will be carried out by carefully planned merging of systems and properties. The public ultimately will benefit from these operations, as it has in the past, by receiving better service at a lower cost as the consumption of energy increases.

### FUTURE GROWTH

That there is in prospect an enormous growth for the utilities serving the states of Ohio, Indiana, Illinois, Michigan and Kentucky is inevitable. Looking into the future, it would seem that they are but on the threshold of a vast expansion program.

Past experience shows a steady increase in population, which may be expected to continue and bring added service responsibility to the electric utilities. But volume of new customers as such will probably be the least source of additional load. The industry will have to concentrate its efforts on more intensive development of existing loads. In the last six years the per capita consumption of electric energy has almost doubled. Industrial applications and uses for power are increasing and many large industries are finding it most profitable to purchase their power requirements from the electric utilities. Further electrification of the railroads is imminent. Commercial, street and highway lighting intensities are mounting higher and using more energy. Domestic use of energy is still largely undeveloped.



*Increase in ratio of customers to total population, 1921 to 1927*

These general conditions and trends alone indicate the necessity for the electric utilities ever to be building in advance of these demands and to anticipate, in so far as possible, use potentialities.

It has been estimated that by 1950 the total consumption of energy in the territory would be 54,000,000,000 kw.-hr., with a coincident demand upon generating stations of 13,500,000 kw. This would require an installation of about 15,000,000 kw. total capacity to provide ample reserve. Based on these estimates of consumption and increased population the combined consumption for all uses would, in 1950, amount to 1,650 kw.-hr. per capita. Viewed in the light of the progress that has been made in the last six years it is hazardous to predict what may happen, but it seems safe to say that any available estimates of future growth that have been made thus far are ultra-conservative.

# New England Optimistic

### Progress in engineering, management methods and commercial activity points to greater triumphs in store with mutual benefits to companies and public

By Howard S. Knowlton

*New England Editor*

IN THE year 1919 the power companies of New England faced many problems. Prices of material and labor had risen to levels which strained the resources of the ablest management to overcome without burdensome increases in rates. Plants had expanded far beyond pre-war ratings and the trend of future loads was uncertain. Interconnection had made a good start in demonstrating its economic value as well as its military necessity, but comprehensive plans for further development were in an embryonic stage. Individual management prevailed in companies serving many important areas, and the holding company had not hit its stride in the advance of the regional industry toward widespread centralization. Personnel was more or less disrupted in organization and effectiveness by the demands of the war. Relations with the public were good but casual as compared with present conditions. Promotional rates were little known and commercial activity was extremely spotty in character and location. Executives were beset with difficult questions of policy, as to financing, engineering, load building and many other matters upon the wise handling of which depended the economic prosperity of the operating properties and to a large extent the success of the communities served by them in the readjustment period immediately following the conflict.

At the peak of the price curve in 1920 the transition of New England from a wartime basis of plant development and operation was well under way, and in this transition the utilities have played an outstanding part, carrying on through years of economic stress and contributing invaluable service to their territories. If electrical methods were absolutely necessary to war industries they have been scarcely less so to the manufacturing and business organizations of these states in the post-war era of readjustment. It is no mean achievement of private management to have met the demands of the public in such an unprecedented period so effectively that advocates of government ownership have been able to make little impression upon the popular mind in the northeast; that rates have been lowered all along the line, and the growth of the utilities economically guided to a status of financial stability and earning power surpassing all previous experience.

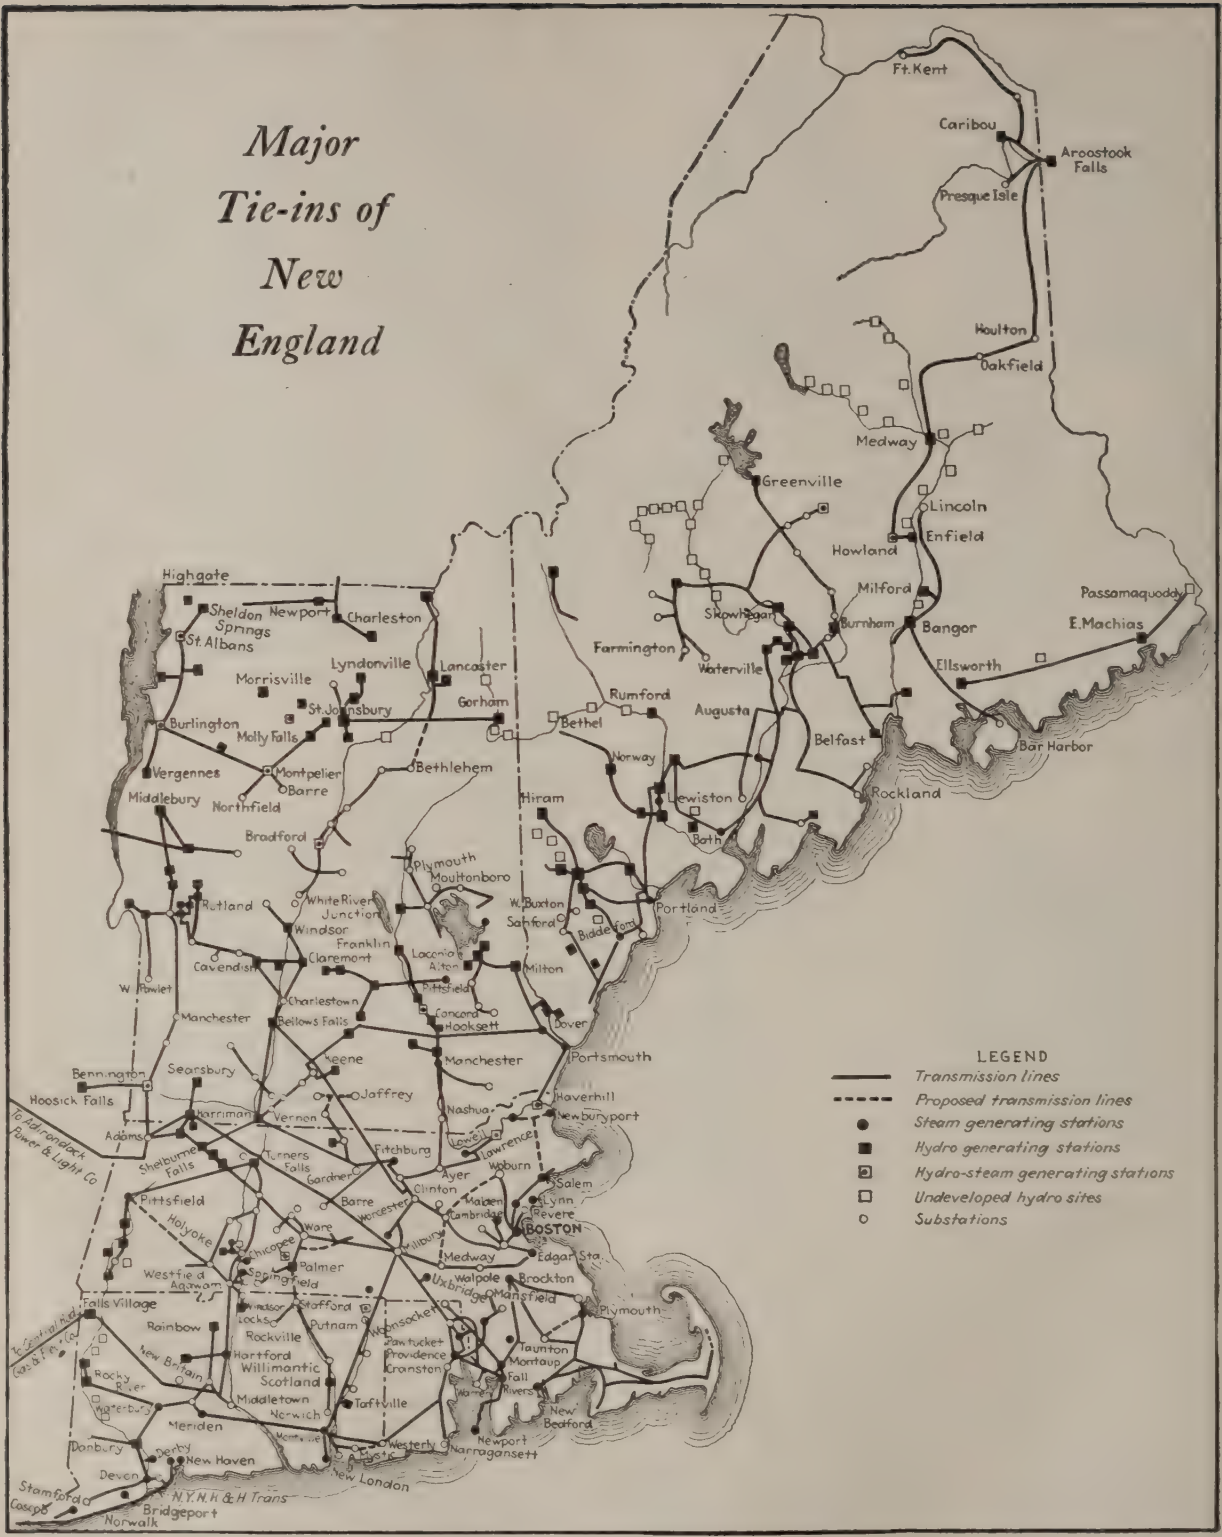
## Diversified Service Required

Maine, New Hampshire and Vermont, the three northern states of New England, embrace large agricultural areas, raw material districts, mountain, lake and river country of marked variety and appeal and many small cities blessed with diversified industries. The three southerly states of Massachusetts, Rhode Island and Connecticut include much attractive farming land and hill country, but in general constitute the major workshop of this region. The railroad trunk lines between Boston and New York are the equivalent of a set of industrial busbars to which are connected diversified factories producing an extraordinary range of commodities in whose creation and distribution electric service is a necessity of the first order. These last-named states contain many cities of rank in American industry and the density of population is such that their effective service by major steam plants on tidewater and by transmitted hydro-electric power from the interior western and northern areas of New England is desirable business.

## Interconnection Progresses

This interconnection of interior plants with tidewater stations by transmission systems has made remarkable strides since the war, and with the exception of Maine the New England States are interlinked with resulting advantages in the utilization of plant investment, transfer of energy to load centers, supply of power during emergencies, marketing of secondary hydro power, use of diverse river flows and decentralization of industry. Maine's law prohibiting hydro power export bids fair to be repealed or modified within a few years at the latest, and when this is done many millions of dollars will undoubtedly be invested in hydro-electric and transmission developments in the Pine Tree State to enable surplus power to be marketed outside and intrastate industries attracted, served and developed on a scale much beyond the present status. Comprehensive plans have been drawn for the development of water powers in the Penobscot and Kennebec Valleys and the construction of trunk transmission lines from central and southern Maine to connect with eastern Massachusetts systems and load centers. These plans include lines from the Passamaquoddy Bay tidal power development in case this works out satisfactorily. Still farther afield, the proposed hydro-electric developments in the St. Lawrence Valley and various projects in Quebec are being studied by New England utility engineers and executives in relation to possible future interconnection with the transmission networks planned and already existing on the American side of the frontier.

During the past seven years many important lines have been built in New England with the objective of interconnecting plants, systems and load centers. Among these are circuits tying the New England Power Company system to that of the Edison Electric Illuminating Company of Boston; a 110-kw. trunk line from the Harriman station of the former company to its load-dispatching center at Millbury, Mass.; a new line from



*WITH the exception of Maine, every New England state is now interconnected with its fellows by important transmission lines. Recently built 110-kv. trunk lines connect the Adirondack system on the west with the Edgar station near Boston, and the new Bellows Falls plant of the New England Power Company in Vermont with eastern Massachusetts load centers.*

Bellows Falls, Vt., to Pratt's Junction, Mass.; lines connecting the New England and Connecticut Company systems with those of the Adirondack and Central Hudson companies; a tie between the Turners Falls Power & Electric Company system and Hartford, forming the trunk connection of the Connecticut Valley Power Exchange; a line from Turners Falls to Pittsfield, Mass.; a line across southern New Hampshire from Keene to Dover, and a line across southern Connecticut from Meriden to Montville. Many shorter lines have also been built, so that today substantially all important properties in central and southern New England with the exception of the United Illuminating Company of New Haven are interconnected and in many cases are negotiating or planning for still further interchanges of energy. Many municipal plants purchase and distribute energy transmitted by this central network of 110 and 66-kv. lines. In Maine important line construction has taken place in connection with the expansion of the Bangor Hydro-Electric Company's system northeast of Ellsworth and in relation to the marketing of power from the Gulf Island development of the Central Maine Power Company. Interconnection of the Central Maine and Portland systems has also been effectively achieved.

### MERCURY VERSUS STEAM

Outstanding developments in generating station design in which pioneer work of the first order has been done may be credited to New England during the post-war period. The most conspicuous are, of course, the 1,200-lb. Edgar steam plant of the Boston Edison Company at Weymouth, Mass., and the mercury vapor installation of the Hartford Electric Light Company at Dutch Point, now being followed by a 10,000-kw. (plus 10,000 kw. in steam production from the mercury process) unit at the latter's South Meadow station. The Edgar station has produced energy upon a fuel consumption of 1 lb. or slightly less per kilowatt-hour, and the Hartford installation points the way toward still further fuel economies on a large-scale plant basis. The executives and engineers of each of these companies are backing their convictions as to the over-all merits of these two systems of power production by appropriating substantial funds for their further installation and expansion. Both processes have passed beyond the experimental stage and the race is settling down to a contest in which service results on a large scale and economic performance, including all costs and charges, will be most instructive to the producer of mass power from fuel. Other important steam plant construction, such as the Devon station of the Connecticut Light & Power Company, the Somerset station of the Montaup Electric Company near Fall River, Mass., and the rehabilitation of the South Street station of the Narragansett Electric Company in Providence can only be given passing mention at this time, to say nothing of betterment and new construction work at Portland, Lewiston, Lynn, Salem, Bridgeport, Stamford and other tidewater points. The trend of the times is away from interior fuel-burning plants in this territory, with few exceptions, the formula being "steam power production at tidewater plus hydro power in the hinterland.

Notable hydro-electric plant construction of the past seven years in New England includes stations at Gulf Island, Me.; Davis Bridge and Bellows Falls, Vt.; Searsburg, Vt.; Sherman, Vt.; Glen (near Rutland, Vt.); Holyoke, Mass. (Holyoke Water Power Company); Mollys Falls, Vt., and Rocky River, Conn. A force of engineers is at work on the tidewater project at Passamaquoddy Bay. Studies are being made of many undeveloped sites in northern New England and Maine. When co-ordinated with the fuel-burning plants on the seaboard these hydro developments usually prove advantageous from the operating standpoint and potent factors in fuel saving.

### LOAD BULDING PROBLEMS

From operating residential cellar stairway pilot lights and curling irons to driving locomotives in main line electrification and melting brass in the crowded industries of the Naugatuck Valley, central-station service in New England exhibits a range of great usefulness. During these past few years leading companies have increased their residential kilowatt-hour sales from, say, 250 per year to 400 and over per metered installation. Sales energy is now concentrated upon increasing domestic consumption through promotional rates and vigorous appliance merchandising. A few venerable utilities still remain unconvinced that appliance merchandising is a desirable central station function, but general industry opinion in Yankeeland is all the other way. Electric refrigeration is making rapid progress and electric cooking is winning headway, some very notable hotel installations having been made of late. Several utilities now are selling electric appliances at the rate of from $500,000 to $750,000 worth per year.

Many pages could be written about the progress of New England in industrial power and electric heating applications if space allowed. The sale of electric motors in New England from week to week often exceeds the $50,000 mark, and the shifting tides of fashion, changing demands of the market for commodities, rehabilitation of factories and attack on industrial and mercantile wastes create a constant market for modernized power units and improved control equipment. In the past six years a single industrial power sales department of a utility organization increased the connected power load 29 per cent, increased the power sales in kilowatt-hours 89.5 per cent and increased the power revenue 116 per cent. In the Naugatuck Valley of Connecticut as far back as 1924 about 90 per cent of the brass melting was done electrically and about 50,000,000 kw.-hr. per year was consumed in this work. The varied metal-working industries of lower New England are rapidly adopting industrial electric heating for approved processes, and in Boston, Worcester, Hartford, Rhode Island and many other places pioneer work has been done in this field with resultant large-scale commercial progress. The central stations have contributed largely to the betterment of working conditions and control of quality production in countless industrial plants by power, heating and up-to-date lighting installations.

Seven years ago commercial activities in New England utilities were less well organized, policies were almost as varied as the personalities of the executives in control, rates were going along without much regard to inducement features and the regional interchange of ideas among sales forces was not much in evidence except among the fortunate few whose expense accounts were allowed to reflect convention attendance. Conditions have now greatly improved. Staffs have been increased and leadership organized for more intensive coverage. Through N.E.L.A. activities and encouraged association of specialists from different parts of New England for the discussion of field methods load building has attained a new impetus. Commercial and industrial lighting has made great strides within the past few years as a result of the organization of divisions of sales departments to push this class of work. Prior to 1920 the value of systematic development of commercial lighting was far less generally appreciated. The prize-winning work of the Boston Edison Company in this field has received national recognition.

### HOLDING COMPANIES INCREASE

Within the past three years many "old-line" New England power companies have been acquired by holding company or management groups. The upheaval of this movement is still undulating and the industry is still in a transition stage from an era of individualized management to a period of centralized management. The so-called "independent" companies are gradually either being acquired by groups or are participating in the holding company movement. A goodly number of these properties remain intact at this writing, but scarcely a week passes without news of some advance toward group operation in this or that locality. The results of centralized management are attracting interest everywhere, and it is a fair statement that many areas in New England are now obtaining improved service at rates which would have been out of the question under the old régime

---

# *Non-Exportation Law Results in Waste*

*An Interview with*

***Walter S. Wyman***
*President Central Maine Power Company*

*Walter S. Wyman*

"DURING the past winter the Central Maine Power Company has had a large amount of water power go to waste. At the beginning of 1927 we estimated that we should have a surplus of about 125,000,000 kw.-hr. during the year. As a matter of fact, the total amount going to waste last year was 131,000,000 kw.-hr. The same proportional waste has continued through the first quarter of 1928. This means that if we had business to use all the energy which our water-power plants could produce the present waterwheels and generators could have turned out 131,000,000 kw.-hr. more than they did.

"At the present time quite a few candidates for political office are saying a lot about Maine's water power and about the importance of 'keeping this priceless heritage for our children's children,' and so on. One of their favorite expressions is to question whether there is any surplus or not, and beginning with that question they conclude, presumably from sources of information which are available exclusively to them, that there is no surplus, so that there is no real need of exporting power. Regardless of this, however, it is a fact that there was a developed surplus on the Central Maine Power Company property in 1927 of 131,000,000 kw.-hr., and while I have no accurate information on the subject, I know enough about the situation to feel very confident that if the power wasted by the other companies in the state were added to this amount the total power going to waste at the plants of the Maine public utility companies in 1927 was more than 200,000,000 kw.-hr. Had the companies been able to sell this waste power their expenses at the power stations would have been no more than they were. Whatever revenue could have been obtained from this sale would have gone to cut down the expenses of the power companies and make more rapid rate reductions possible.

"It is true that not all of this power is available every day in the year, but this does not detract from the business importance of selling it. Since the 1927 Legislature adjourned more than 4,000,000,000 kw.-hr. has gone to waste on the undeveloped portions of Maine rivers. It will be many years before this very large amount of power could be used in Maine. Much of it might be developed and used during the next few years if it were possible to export the surplus. To say that this power, once exported, will never afterward be available for use in Maine seems the rankest kind of nonsense. All the other states in this country are allowing free passage of electricity across their borders. Many of them are prospering to a far greater degree than Maine. In no case has export deprived the local market of electricity. If export were permitted, the state of Maine might realize in taxation alone from $500,000 to $1,000,000 a year. We would have available and ready for use sufficient cheap power to attract large power-using industries, and Maine might begin to produce the raw materials used in many kinds of industry. Business in the state would go forward with no uncertain step; labor would find employment in large amount. All these things could happen without changing in any way the 'heritage of our children's children.'

"This matter of changing the state's policy in regard to exportation of power is extremely important. The law as it now stands seriously hinders our industrial progress. I have expressed the hope to our stockholders in very much the above language that they will make their influence felt to have this law changed, and the widest possible publicity of the facts in regard to this situation is desirable in order that a way may be found to remedy this great economic loss."

of local control. New generating plants and lines have been financed by more and more holding companies with great benefit to the regions served, and a vigorous effort to reach the rural customer is apparent in many localities formerly debarred from adequate line extensions. The remaining large independently operated companies, however, include some of the strongest, finest equipped and best managed utilities in the industry, and it would be farcical at this time to blow "taps" over the camp of isolated management. Thus far New England's experience with the holding company, whether "home ruled" or "foreign," has generally been encouraging and promising. In most cases the new interests have had the wisdom to capitalize the experience and local standing of competent managers and staffs already on the properties. The combination of technical, financial and managerial resources resulting from the correct application of the holding company principle has opened the pathway toward development often beyond the capacity of the isolated property to attain. Many problems, however, remain to be solved by each type of management, and the next few years will probably witness striking progress toward the common objective of each—maximum service at fair rates under the best modern methods.

---

# *Utilities Advancing in New England*

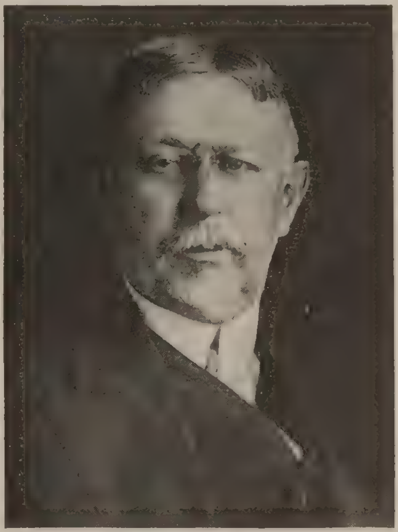
*An Interview with*

*Charles L. Edgar*

*President Edison Electric Illuminating Company of Boston*

"NEW ENGLAND utilities have progressed in so many ways since the close of the war that it is not easy to pick out their foremost achievement," said Mr. Edgar in response to a request by an ELECTRICAL WORLD representative that the dean of the industry in the Northeast give his impressions of regional electrical development since 1920 to the readers of this publication. "Growth along nearly all major lines of usefulness is perhaps the outstanding point which we may stress. New England is an old section of the country, undergoing many changes, but nowhere has the electrical industry been of more assistance in facilitating the development of new methods in manufacturing, in improving ways of doing business and in enriching living standards. The industry has prospered in this expansion, and it is today serving the public, broadly speaking, at prices not only far below the line of cost increases forced in other industries by the World War but generally under pre-war levels. There is reason to believe that the public at large is becoming 'price-conscious' in this sense."

"To what do you attribute this popular recognition, Mr. Edgar?" asked the ELECTRICAL WORLD editor. "It would be a mistake to overemphasize this change of feeling or, rather, growth of understanding by the public," replied the head of the Boston company. "The public relations work of the industry has been far-reaching, and the reiteration of the significance of the price trend in light and power circles is bearing fruit. Within the industry it is well known that we are continually striving to produce, transmit and distribute energy at lower over-all costs. Success here enables operating companies to institute rates which encourage greater use of service. Slowly but certainly the public is coming to appreciate that while the light and power stockholder's investment is entitled to a return which will attract new money for the upbuilding of the business, after all proper costs and charges are met and a surplus provided against future needs, wise management is striving to achieve rate levels that will develop volume business, whether in the home or in the factory. Of course this cannot be accomplished in a day, but the trend is toward a time when unfair attacks upon rates will be less frequent."



*Charles L. Edgar*

Mr. Edgar's attention was then called to the many problems of post-war readjustment which all industries have had to grapple with, and he was asked how the light and power companies of New England have been able to meet these conditions. Turning to his questioner, he said: "By taking advantage of improvements in equipment, by interconnection on a widening scale, by economies in operation, load building, prudent financing, and through the more skillful and analytical planning of system development savings have been made and business increased very substantially on leading New England properties. The policy of centralized operation has gained further headway, both in singly managed and grouped systems. The volume of service to the public represented in present energy sales and the increased amount of wholesale power blocks marketed regionally over intercompany tie lines indicate that comparatively speaking we are in an era of electrical mass production and distribution. This means that we can well afford to utilize the most advanced engineering ideas, support vigorous commercial policies, co-operate with other branches of the electrical industry to stabilize and safeguard profits, back up sound educational programs for employees, maintain more valuable contacts with other industries and in many cases play a valuable part in what might be called corporate community citizenship. New England utilities have been on the alert, for the most part, in making use of progressive ideas. Some companies have pioneered developments which are already making history, and interest is widespread in the results of such advanced installations as the high-pressure steam units at our own latest station and the mercury boiler and turbine application at Hartford."

"Mr. Edgar," said the representative of the ELECTRICAL WORLD, "has hydro-electric development in New England in any way threatened the basic value of steam plants of large capacity in this territory? Is there any reason to expect that steam plant development will cease to maintain its key position here as interconnections with distant waterpowers grow in number and transmitting capacity?" "We have in New England," was the answer, "an unusually good instance of the advantageous working together of both steam and hydro plants. For many years the public overestimated the value of water powers, but intelligent popular opinion today grasps the fact that many of these represent larger outlays per kilowatt of rating than do the later steam stations.

### STEAM AND HYDRO CO-ORDINATED

"The readers of the ELECTRICAL WORLD appreciate the economic benefits of interconnections between steam and hydro plants, and these need not be repeated. General statements of the value of water and steam plants carry little weight, but the system interconnections which have grown up in the past decade or so have added to the economic position of the tidewater steam stations of New England. Secondary hydro power has found a wide market when brought into the urban system load centers. Problems of interoperation have been many, but these are being attacked by engineers with good results. Taking the two kinds of plants together, it is a fair statement that thus far many economies have been reaped in this region from their association, and we may expect more to follow. Unquestionably some steam plant expansion has been postponed on account of hydro interconnections, but I am sure that we shall continue to purchase fuel-burning apparatus for large-scale electric generation.

"Present-day improvements in equipment and in methods," said Mr. Edgar, "proceed with a clear vision of our over-all cost responsibilities. In New England, as elsewhere in the United States, we are confronted with the necessity of working the invested dollar harder. Progress is apparent in many fields of load building from the home to the industrial plant. It is safe to say that through electric refrigeration, cooking, better lighting and in many other ways the average annual energy consumption of the home in New England will make great gains over present figures within the next few years, even as the present consumption much exceeds that of pre-war days. I doubt if many New England companies sold over 250 to 300 kw.-hr. per home per year before 1920, whereas today quite a number have reached 400 or over and 500 does not appear far off as a base, and in fact will become common as the full drawing power of promotional type rates becomes felt. This whole question of utilizing our capital investment more effectively is a very large subject. It receives constant study, and every diversified application of electricity that is established promotes it. It is intimately related to commercial activity, and New England's progress in industrial lighting, industrial electric heating, more efficient applications of electric power in old and new installations during the past seven years has been made in full recognition of the industry's investment responsibility."

"In connection with these improved methods," asked the ELECTRICAL WORLD man, "the question has arisen as to whether the property under holding company operation has an advantage over the singly managed company. I do not suppose the question can be answered categorically, but I think it would be helpful if you would say a word on this." "It is a question of methods rather than who applies them," said Mr. Edgar. "It is apparent that small, independent properties run under a considerable handicap, although public relations are good in many of these and some are doing an excellent job in the distribution field. The trend is toward centralization in management, but we obtain this on some of our larger singly run properties scarcely less than in holding company groups. The Edison company of Boston developed its present system by acquiring a large number of small suburban properties, shutting down wasteful generating stations and co-ordinating them with the metropolitan organization. Both types of property are illustrated in successful management. It is sometimes overlooked that there is an interchange of ideas and experiences throughout the electrical industry that is not confined to holding companies or to so-called independent properties, and it might be correct to say that the future depends more upon the quality of management rendered than upon ownership. So far as the public is concerned, a certain decentralization of company administrative functions will be necessary regardless of developments in ownership, in order to maintain understanding and friendly relations with localities and their individual interests. It is obvious that where securities can be bought and sold in the open market, properties may change owners. Many such changes have featured electrical development in New England since the war, and no one but a prophet can foretell how far this movement will go. In New England you can point to excellent relations between properties of each type."

### AN OPEN BOOK POLICY

"Could you not fairly say, Mr. Edgar," was the final question, "that the open book, as it were, of the light and power companies' policies and the desire of company managements to help build up prosperity in New England through every reasonable form of co-operation have powerfully influenced the successful development of the industry in these past few years? In other words, is not the effort to render public service in the best sense of the word fundamental? "It should not be necessary," said Mr. Edgar, "to elaborate this. It is simply fundamental to modern ideals of public service to build up friendship between ourselves and our customers by rendering the best service we can at reasonable rates. If the industry as a whole in New England had not done this in the past few years, it would have lost a large proportion of its business. A major reason for establishing the Boston Edison radio station, WEEI, was to build popular friendship. In all our activities, from serving the rural customer at the end of a costly line extension to co-operation with the New England Council in its constructive work for the development of these six states, from serving metropolitan industries to supporting worthy industry organizations, the utilities of this section are working in the open, and have long done so. The past seven years have been marked by many technical advances, but none has been of greater import than the quickening sense of responsibility among ourselves, our customers and the public in general which has yielded so much good."

*Birmingham is typical of a rapidly growing industrial city of the South*

# The Interconnected South

Industrial renascence of the South makes for wealth and social progress. The big five program gets results. Electric power the keynote of success

By L. W. W. Morrow
*Managing Editor*

THE renascence of the South is the most eventful happening of current American progress. This region lay prostrate for 40 years following the Civil War and upward of 8,000,000 discouraged young men left the South to seek their fortunes in a more favorable environment. What has happened to awaken the South and to make it the land of promise for American business executives? Why has the value of manufactured products increased in the South from $1,394,316,000 in 1910 to $4,754,824,000 in 1926? Why is the rate of industrial and commercial growth in the South greater than in any other region in America and why has the social progress of this region kept pace with its industrial achievements?

The traditional South is advancing one and one-half times faster than the country as a whole, according to a recent survey of the Department of Commerce. It has led the nation in industrial and commercial growth during the last twelve years and the basic factors for this growth are given as electric power, agriculture, mining, forestry and manufacturing, together with the fact that it is a region favored with splendid topography, a good climate, many natural resources, an abundance of raw materials, an ample labor supply and is near enormous domestic and export markets. Very largely it is a case of capital and industry going to power and labor under favorable taxation conditions.

About 1910 the South found the big five program which it follows today and the practical application of this program has brought about the astonishing progress of recent years. The big five program is the co-ordinated and active development of

1. Electric power.
2. Educational facilities.
3. Good roads.
4. Manufacturing industries
5. Diversified agriculture.

It is not exaggeration to say that the renascence of the South is largely a byproduct of technical electrical progress. Through the pioneering efforts of the utilities electric power was made available in all sections of the region and this power has brought industry to the workers and has made possible social progress.

Electricity completely reverses the older process of taking the worker to the power. Few students of industrial civilization realize that the steam engine age of power has gone and that no longer is it necessary to have congested cities, enormous factories and concentrations of mechanical power in one locality in order to obtain economic industrial development. Electricity can rush with the speed of light to the place it is needed, and through the most extensive and complete interconnected transmission system in the world the old South has coordinated its fuel and hydro power resources and sent them forth to diversify industry, to attract new industries and to raise the standards of comfort on the farm and in the home.

Electric power has been made ready for the industrial South. In case of need electricity can be relayed from Tennessee and Alabama to eastern North Carolina or Virginia, 600 miles distant, or power can be relayed from West Virginia to Alabama and Mississippi. Complete flexibility in transmission has been developed and the co-ordinated resources of the utilities are placed in service in any locality as needed to meet economic conditions. The waterpower installations aggregate more than 4,000,000 hp., and it is estimated that more than 3,000,000 hp. in new water-power installations will be added to meet the power demands of 1933. Added to this is an equal amount of fuel-burning station capacity so that the combined fuel and hydro power installations are expected to aggregate more than 12,000,000 hp. by 1933. In 1928 the nine Southern states listed in accompanying tables had 1,291 operating light and power companies with an aggregate generating capacity of 4,241,000 kva.

The waters on the eastern slope of the Appalachians and those of the western slope have been harnessed to the fuels of West Virginia, Kentucky and northern Alabama to afford an economical and flexible power supply to a region which has just awakened to its future despite the rapid growth of the past few years.

Utility executives in the South had the vision and courage to build this interconnected system to bring to the South new industries to use the power available. They went to industrial centers to sell the South, they worked with Southern town officials to show them how to build up their communities by co-operating in an industrial program and in many instances they went so far as to invest their money in new business enterprises. A romance in utility pioneering could be written of the South, and when recent history is recorded it will be found that the cornerstone of the new South was the initiative, faith and ability of these utility executives.

Good roads in the South have called for about $400,000,000 a year for several years and these roads have helped to change the entire agricultural and industrial situation. Farmers can market their crops and can get ready money by helping to build the roads; each town and city is accessible to workers who dwell in the rural areas and tourists now drive South in winter to add new money and to bring new business. Good roads have brought about accessibility and have developed a community of interest in co-operative projects for the benefit of the states.

Education has had a revival in the South in marked degree. Leaders of the South based their program for progress on the development of a sound educational system, and in most of the states today public schools and colleges are found that are well conducted and supported. Education has become a paying commercial project as well as a desirable cultural development.

### BASIC RESOURCES OF SOUTH

Down through the Appalachian mountains and their foothills, extending from Pennsylvania to Alabama, lies the manufacturing region of the South. The mineral deposits, the raw materials, the best labor supply and the most favorable geological and geographical conditions are found in this area.

The leading manufacturing industries in the South are lumber, textile, furniture, iron and steel, quarries, tobacco and cement. A wave of popularity for textile manufacturing has resulted in the location of 18,399,832 cotton spindles in the South, compared to a U. S. total of 36,494,496 in 1928. In 1927 the South had a net increase of 502,210 spindles and the other states had a net decrease of 1,372,444 spindles. These spindles in the South work more spindle hours per year than those in other areas because statistics show that Southern mills, with 50.42 per cent of the spindles, worked 65 per cent of the total spindle-hours recorded in 1927. These textile mills are scattered over the Piedmont region of the South, where good labor is available and where climatic conditions are splendid. Many rayon mills are being built in this region to take advantage of these conditions.

In the Birmingham district the South has developed large metal, electrochemical and coal mining industries. The Tennessee Coal & Iron Company has very large metal-producing and coke-producing works near Birmingham and many allied types of industries have been constructed in this region because iron ore deposits, coal beds, shale deposits and limestone deposits are found. Cement mills and fertilizer plants occur in numbers and diversified manufacturing is very evident in central Alabama.

In western North Carolina near High Point one of the largest furniture manufacturing areas is now found. Southwest Virginia, southern West Virginia and western Tennessee are witnessing a very rapid growth of manufacturing, textile, electrometallurgical and electrochemical plants predominating. The Aluminum Company of America has large plants at Badin, N. C., and Alcoa, Tenn., and is enlarging its production facilities in the South. Many Southern manufacturing plants have been the result of local enterprise, but in a number of instances industries have been brought to the region solely because the industrial departments of the electric utilities have gone to manufacturing centers and brought new industries to the South. The genius of James B. Duke started the early development of textile and tobacco manufacturing in the Carolinas and many other utility executives likewise adopted a very aggressive industrial policy.

In the Kanawha Valley of West Virginia a large electrochemical and electrometallurgical industry has sprung into being and in eastern Tennessee rayon and textile manufacturing is growing fast. The ample power resources and the stable and competent native white labor combine with climate, natural resources and transportation facilities to make this region the center of this type of manufacturing.

### *Economic Progress of the South**

*States of Alabama, Florida, Georgia, Mississippi, North Carolina, South Carolina, Tennessee, Virginia, West Virginia. Based on *Census and Manufacturers' Record* data.

Between the foothills and the coastal plain lies a very fertile agricultural area where diversified agriculture, dairying, fruit growing and other industries are very promising under the new conditions, and down in the coastal plain lies a fertile belt for forest products, agriculture and manufacturing which can use negro labor to advantage. Almost any climate and any environment can be selected in the South to suit the business of any prospect and it is astonishing to find that these possibilities were unrecognized a dozen years ago.

Cotton is still king in the South, but the center of cotton growing is shifting to Texas and Oklahoma and more diversified agriculture is taking place in the old South. In south Georgia peaches and pecans predominate, in north Georgia apples are grown in large quantities. In Florida the citrus fruits of the lake regions will soon be challenged by the vegetable products of the truck gardens in the reclaimed Everglades. In the black hills of Alabama and Georgia the dairy industry is developing and in northern Florida, the Carolinas and other states general agriculture is being developed with crop diversification as the keynote to progress. The farm crops of the South in 1926 were worth $1,522,000,000.

In agriculture, as in manufacturing, the influence of electric power is felt decisively. Rural lines are built in all sections and a reliable source of electricity is available in nearly every village and cross-roads community. The farmhouse will soon be made comfortable with light, telephone and electric appliances and many electric ranges and water heaters are used. Co-operative work is going on in all states to bring the electric motor to do the work of the farm. Electric power, good roads and good rural schools keep competent farmers on their farms.

The South of today is capitalizing on the errors made in earlier industrial developments. It is rapidly proving that decentralized industries lend themselves more effectively to the economies of mass production than congested areas with enormous factories. Electric power, raw materials, a small plant and a small town with surrounding farms to feed the workers are proving to be a better industrial and social arrangement than any heretofore established. The South is finding the answer to the mechanization of civilization.

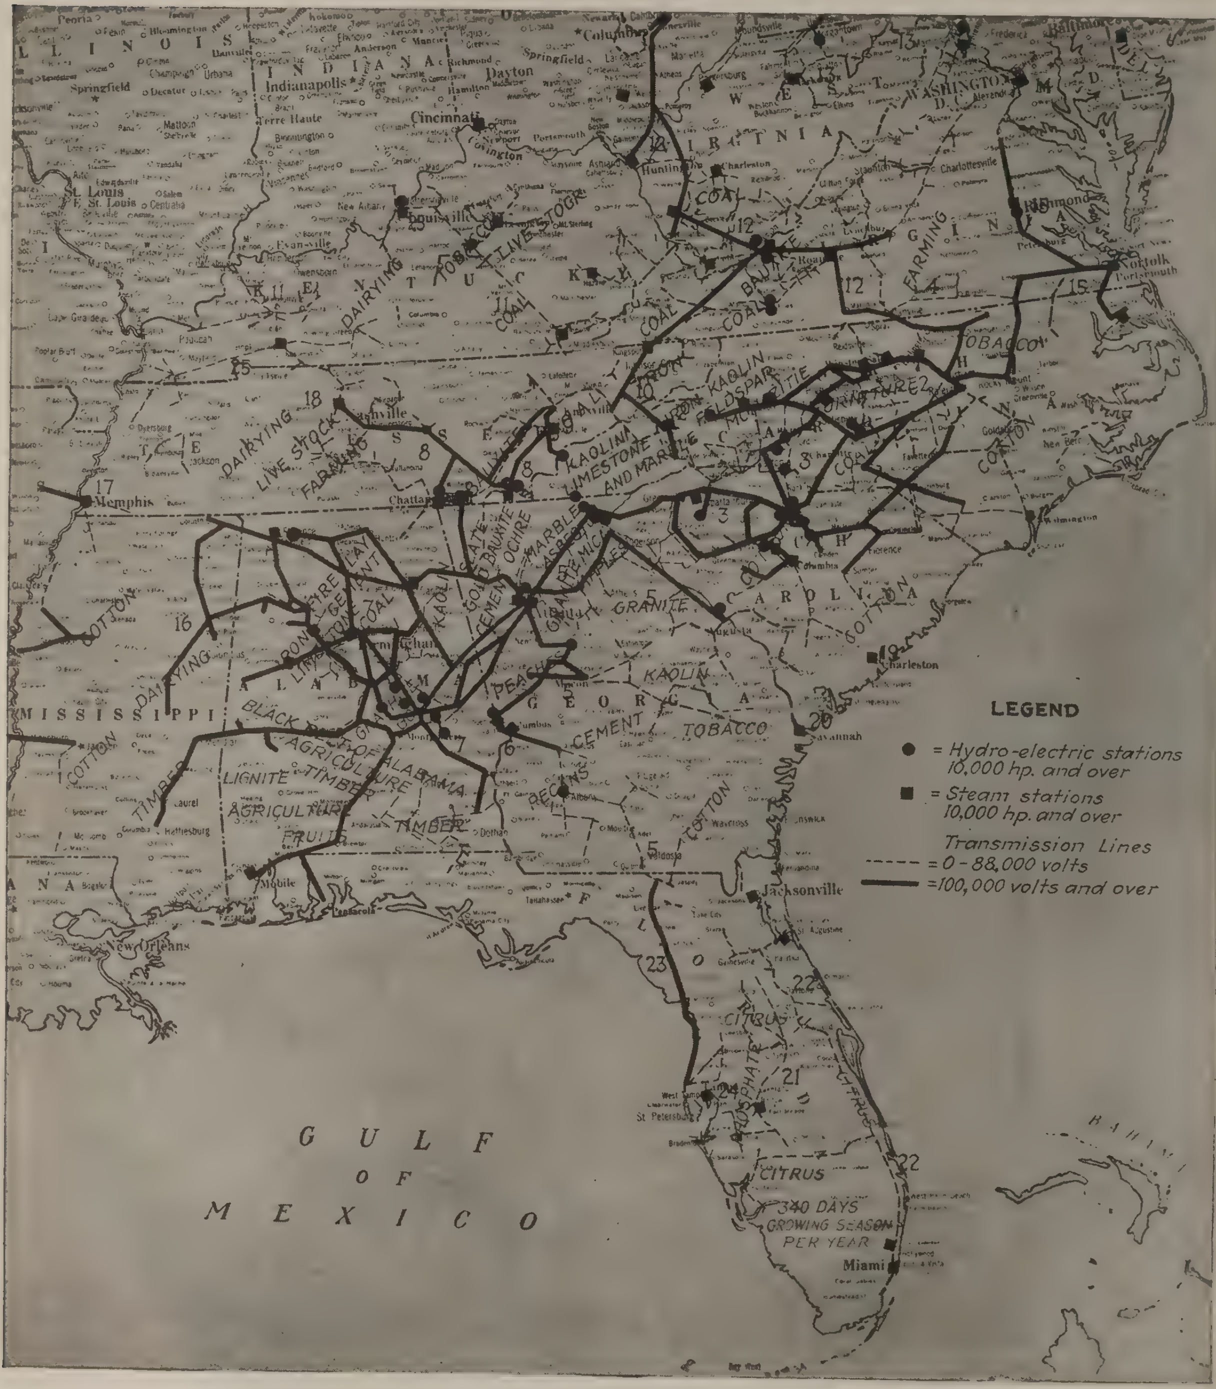
The light and power industry in the South has entered upon a new period of development. The rather small scale operations of local utilities are replaced by very large scale operations wherein multiple hydro and steam stations are tied to widely extended transmission systems. Along with this physical property development is the growth of a load-building and industrial policy whereby the utilities use every effort to bring new industries into the territory and to develop existing industries.

Fortunately these transitions were easy and logical, for they followed hard on the growth of local hydro-electric properties which were interconnected with adjacent utilities. The utilities of the South started largely as hydro properties serving distant cities over transmission lines. Because of the variable water flow in most Southern rivers the interconnection of utilities was a self-evident service insurance and was used as normal practice. The grouping together of utilities under one management and the co-ordinated use of steam and hydro stations was a logical step to take in the further electrical development of the territory. Today finds the South largely served by the following utilities:

Southeastern Power & Light Company.
Carolina Power & Light Company.
Duke Power Company.
Florida Power & Light Company.
Tennessee Electric Power Company.
Appalachian Power Company.
Virginia Public Service Company.

There is a very interesting interconnection between utilities in the Carolina region. The Duke Power Company has hydro plants along the Catawba River and several steam stations. The Carolina Power & Light Company has hydro stations on the Yadkin, a large steam

# *Electric Power Is Available to Develop All the Resources of the South*



## PRINCIPAL OPERATING UTILITIES IN THE SOUTHEAST

1. Tidewater Power Company.
2. Carolina Power & Light Company.
3. Duke Power Company.
4. Virginia Public Service Company.
5. Georgia Power Company.
6. Columbus Electric & Power Company.
7. Alabama Power Company.
8. Tennessee Electric Power Company.
9. Knoxville Power Company.
10. Tennessee Public Service Company.
11. Kentucky Utilities Company.
12. Appalachian Electric Power Company.
13. Monongahela West Penn Public Service Company.
14. Potomac Edison Company.
15. Virginia Electric & Power Company.
16. Mississippi Power Company.
17. Memphis Power & Light Company.
18. Nashville Power & Light Company.
19. South Carolina Power Company.
20. Savannah Electric Company.
21. Florida Public Service Company.
22. Florida Power Company.
23. West Florida Power Company.
24. Tampa Electric Company.
25. Louisville Gas & Electric Company.

plant at Cape Fear and small hydro steam plants near Asheville. The Tallahassee Power Company has hydro plants on the upper Yadkin which largely supply energy to the Aluminum Company at Badin. On the north the Carolina Power & Light Company has an interconnection with the Appalachian Power Company, which in turn has a connection with the Tennessee Public Service Company, which in turn interconnects with the Asheville-Carolina system.

By means of these interconnections many emergency and normal energy interchanges occur. This winter, when extremely cold weather limited the capacity of hydro plants at Asheville, energy was relayed from the Raleigh property via the Appalachian Power Company and the Tennessee Public Service Company. This enabled Asheville to carry its load without curtailment.

### *Growth of Typical Carolina Utilities*

| | 1921 | 1927 |
|---|---|---|
| Duke Power Company: | | |
| Total generating capacity, kva....... | 280,900 | 902,395 |
| Circuit-miles of high-tension line...... | 2,143 | 3,803 |
| Kilowatt-hours generated............ | 834,300,000 | 1,750,000,000 |
| Population of territory served........ | 1,650,000 | 2,000,000 |
| Carolina Power & Light Company: | | |
| Total generating capacity, kw......... | 34,525 | 84,710 |
| Kilowatt-hours generated............ | 150,854,366 | 426,425,000 |
| Miles of high-tension line............ | 606 | 1,820 |
| Number of electric customers......... | 25,347 | 63,102 |
| Miles of distribution line............ | 470 | 1,565 |

Again, the Pigeon River hydro project under way near Asheville will deliver a large block of energy to the northern part of the Duke Power system. This system will deliver an equal amount to the Carolina Power & Light system at Wateree, in the southeastern part of the state. Both systems will get needed energy from nearest generating sources to load areas which require the energy. Again, the Carolina Power & Light and Duke Power systems deliver energy to the Tallahassee Power Company to operate the Aluminum Company plants at certain periods and the Tallahassee Power Company returns energy from its hydro plants at other periods, depending upon load and water conditions. Again, it is possible to interchange energy with the Tennessee Public Service Company, the Georgia Power Company and the Appalachian Power Company at intervals, depending upon load and water conditions.

The Southeastern Power & Light Company is the most widely extended transmission system in the South. It operates in Mississippi, Georgia, Alabama, Florida and South Carolina. The larger operating subsidiaries are the Alabama Power Company, the Georgia Power Company and the Mississippi Power Company. The grouping of these properties under one management has been followed by an extension of lines to small towns and rural areas and by aggressive load-building efforts. The co-ordinated operation of many lines and plants has brought about many operating economies and improved service conditions.

For many years the major utilities in Georgia remained in the larger cities and used transmission lines to interconnect with utilities in neighboring states. But at present a rapid integration is occurring whereby the large systems are extending into adjacent territories. The Georgia Power Company has expanded very rapidly since it became part of the Southeastern Power & Light Company and has extended south and east.

Georgia in the north has coal and mineral deposits, including the famous marble quarries. In the central part of the state peaches, pecans and general farming predominate and the coastal plain is suited for timber and general farming. The peach and pecan business has grown by leaps and bounds and apples are being grown in large quantities in the north. The mineral deposits of Georgia are being investigated and a brick and clay industry is also growing rapidly in the central part of the state.

### *Typical Towns on Carolina Power & Light Company System*

1. **Oxford, N. C.**—A town served for many years which has a competing gas company. It has 724 residential customers and 70 ranges are served.

| | 1921 | 1927 | Per Cent Increase |
|---|---|---|---|
| Kilowatt-hours sold to lighting customers................ | 254,414 | 447,525 | 76 |
| Kilwatt-hours sold to power customers................ | 809,740 | 1,863,343 | 130 |
| Kilowatt-hours sold for heating and cooking........... | 66,116 | 100,279 | 51 |
| Number of street lights....... | 55 | 61 | 10 |
| Gross merchandise sales, dollars | 8,655 | 10,447 | 21 |
| Total number of customers.... | 957 | 1,131 | 18.2 |
| Estimated population........ | 4,100 | 6,000 | 47 |
| Miles of distribution line...... | 17.6 | 22.2 | 21 |

2. **Hamlet, N. C.**—A town served for many years. Railroad junction with railroad shops. It has 897 residential customers and 176 ranges are served.

| | 1921 | 1927 | Per Cent Increase |
|---|---|---|---|
| Kilowatt-hours sold to lighting customers............ | 353,874 | 563,669 | 60 |
| Kilowatt-hours sold to power customers................ | 2,360,991 | 3,650,784 | 57 |
| Kilowatt-hours sold for heating and cooking........... | 222,692 | 323,394 | 45 |
| Number of street lights...... | 131 | 187 | 42 |
| Gross merchandise sales, dollars..................... | 9,714 | 10,994 | 13 |
| Total number of customers... | 1,059 | 1,391 | 31 |
| Estimated population....... | 6,100 | 6,800 | 11.5 |
| Miles of distribution line..... | 19.5 | 27.7 | 42 |

3. **Hartsville, S. C.**—Industrial and residential town purchased in 1921. Notable increase in business followed as a result of the service and merchandising efforts of the Carolina Light & Power Company organization.

| | 1921 | 1927 | Per Cent Increase |
|---|---|---|---|
| Kilowatt-hours sold to lighting customers............ | 218,487 | 454,582 | 108 |
| Kilowatt-hours sold to power customers................ | 6,163,554 | 12,149,852 | 97 |
| Kilowatt-hours sold for heating and cooking........... | 61,038 | 222,788 | 264 |
| Number of street lights...... | 104 | 177 | 70 |
| Gross merchandise sales, dollars..................... | 7,211 | 17,166 | 138 |
| Total number of customers... | 659 | 1,231 | 87 |
| Estimated population....... | 4,100 | 4,700 | 14.6 |
| Miles of distribution line..... | 12.7 | 49.1 | 286 |

Georgia utilities in the past have relied very largely on water power and still do because of major interconnections. The Georgia Power Company is linked with the Alabama Power Company at several points, making it convenient to use fuel energy from Alabama and even Tennessee when economical. Atlanta is the chief city on this system and a center of utility activity. This city is a manufacturing and wholesale outlet of the South and is growing rapidly.

### *Growth of Georgia Utilities*

| Georgia Power Company: | 1921 | 1927 |
|---|---|---|
| Generating capacity, kw. | 106,200 | 219,098 |
| Energy generated, kw.-hr. | 246,440,991 | 329,829,017 |
| Energy purchased, kw.-hr. | 35,643,976 | 367,477,871 |
| Total system energy, kw.-hr. | 282,084,977 | 697,306,888 |
| Miles of transmission line | 354.75 | 916.48 |
| Miles of high-tension distribution | 330.01 | 1,341.14 |
| Number of electric customers | 33,222 | 83,637 |
| Population served | 730,000 | 1,550,000 |
| Columbus Electric & Power Company: | | |
| Generating capacity, kw. | 32,200 | 62,255 |
| Energy generated, kw.-hr. | 92,763,490 | 223,597,126 |
| Miles of transmission line | 60.0 | 176.2 |
| Number of customers | 6,267 | 9,900 |
| Population served | 134,350 | 84,467 |

### *Merchandise Sales per Customer on Georgia Power Company System*

| | Electric | Gas |
|---|---|---|
| 1925 | $4.76 | $5.31 |
| 1926 | 10.73 | 5.92 |
| 1927 | 15.27 | 6.09 |

At Columbus the Columbus Electric Company has hydro stations and interconnections with adjacent utilities. It has an extensive transmission system to serve agricultural towns in the southern part of the state. Several textile plants have been located in this region and this industry is growing.

Fourteen years ago the Alabama Power Company had five power customers who had a connected load of 6,000 hp. During 1927 this company operated generating stations with an aggregate capacity of 490,000 kw. and sold more than 1,400,000,000 kw.-hr. to customers.

This growth is typical of Alabama in late years. Coal in the north, iron and limestone in the central portion, fine agricultural lands, low taxes and good labor combined with electric power to build the state very rapidly. More than 2,000,000 tons of iron ore and 6,000,000 tons of coke produced in 1927 attest the size of this industry. Add the cement, coal mining, lumber, electrochemical and textile industries to the pool and it is seen that Alabama rightly can be proud of its accomplishments.

Birmingham is called the Pittsburgh of the South and the records of the Birmingham Electric Company prove that it has had an astonishing growth in the few years of its existence. Montgomery, Anniston and other interior cities have likewise grown rapidly and the development of the port facilities in Mobile bid fair to bring an export outlet of manufactured products which will make Mobile an outstanding city.

Raw materials and natural resources in themselves did not make Alabama growth. The electric utilities developed water and steam power, sent their lines out across the state and then went into the industrial centers of the country and sold their territory and facilities to industrial executives. For 1927 alone the Alabama Power Company secured new industries for the state which will add 30,000 people and $15,000,000 new capital spent for construction to the assets of the state.

There were 1,587,842 cotton spindles in Alabama on Jan. 31, 1928, and many new textile plants are contemplated in the near future because of the efforts of the Alabama Power Company in co-operation with Alabama towns.

Florida has not been injured by the collapse of the boom. This state still has its timber, phosphate, agriculture, fruits and warm sunshine. The tourist crop of 1927-28 was splendid and Florida is equipped to entertain winter tourists properly, thanks to the boom. Hotels are splendid and people with means flocked to the resorts to enjoy the sunshine and recreation facilities.

Central Florida is developing a splendid citrus fruit industry. In the Everglades five truck crops a year are luring gardeners to the region. Near Tampa the phosphate deposits afford a stable industry and in northern Florida general farming, lumber and fishing are splendid assets. The basic soundness of Florida is unaffected by the rise and fall of real estate speculators.

The Florida Power & Light system extends along the east coast and across the country to the west coast to Fort Myers and other towns. It serves 112 communities and 115,000 customers. It was put together in 1925 by closing down many small plants and connecting together these towns by transmission lines, so that today three efficient power stations do the work of nearly a hundred inefficient stations. This company is building its territory even to the extent of establishing an experimental farm in the Everglades. Properly developed, the Everglades will use about 1 kw. per acre for trucking and the utility is doing more than its share in bringing this garden spot into cultivation.

At Tampa the Tampa Electric Company has a very stable load because of the industries in and near that city, especially the phosphate industry and the tobacco industry. This utility reports very good conditions. In the citrus regions near Orlando the Florida Public Service Company has built a splendid system which supplies light and power to a large area from a modern system.

### *Alabama Power Company Grows Rapidly*

| | 1921 | 1927 |
|---|---|---|
| Installed capacity, kw. | 191,675 | 490,051 |
| Circuit-miles of transmission lines | 563 | 1,255 |
| Miles of distribution lines | 989 | 2,763 |
| Number of customers | 17,967 | 67,084 |
| Energy generated, kw.-hr. | 429,110,700 | 864,958,000 |
| Energy purchased, kw.-hr. | 3,878,600 | 445,083,150 |

### *Energy Sales Data of Alabama Power Company*

| Year | Number of Wholesale Customers | Number of Retail Customers | Total Energy Sales, Kw.-Hr. |
|---|---|---|---|
| 1921 | 159 | 18,000 | 370,470,000 |
| 1922 | ... | 20,000 | 511,914,000 |

In northern Florida two municipal plants serve Tallahassee and Jacksonville and the Florida Power Company has built an extensive system from near St. Petersburg north to Jasper, where it interconnects with Georgia-Alabama Power Company systems. The Gulf Power Company serves 9,000 customers in Pensacola and thirteen towns in the surrounding territory and is interconnected with the utilities of the Southwestern Power & Light group.

### CONDITIONS IN TENNESSEE

On the western side of the mountains the Tennessee Electric Power Company operates a large system which has been influential in developing the industrial assets of middle and eastern Tennessee.. In Memphis, Knoxville, Nashville, Bristol and other towns local utilities are alert to every opportunity to get industries to locate on their lines and the executives devote major attention to local building.

Practically all of the industrial development of Tennessee during recent years has been in the territory served by power lines. During the last five years Tennessee, in keeping with the rest of the South, has secured a share of the textile mill business that has been moving away from New England and has developed local plants. These textile mills have all located in the

---

# *Need More Publicity —Not Less*

*By P. S. Arkwright*
*President Georgia Power Company*

IF THERE is one outstanding lesson to be learned from the present investigation of the electric light and power industry by the Federal Trade Commission it is this—not that we should curtail or cease our public relations and educational work, but that we should increase it, expand it, and carry it forward with greater vigor.

It is upon this phase of our work that the attention of the commission has so far been centered, and we have been charged in the sensational press with "polluting the stream of education," with wholesale "corruption of editors and legislators" and with other grand and petty crimes too numerous to mention.

The very fact of these extravagant charges, the unrestraint with which the propagandists for government ownership have sought to give the color of corruption to entirely innocent acts, the complete and utter baselessness of many of the charges are all the proof we need that greater educational work must be done.

We have always been the target of the demagogue. Perhaps we always will be, no matter how we conduct ourselves. Perhaps we should take comfort in the fact that we are better off than we used to be, that our opponents now are forced to base their charges upon actions which further, cooler consideration will show to be blameless.

But events of the recent past have shown how much we have yet to do before the public at large learns to know and really to understand our business, our aims, our purposes, how vital it is to the public itself that private initiative in this industry be preserved, how harmful it is to the public itself when we are saddled with unjust tax burdens and subjected unjustly to political attack.

*P. S. Arkwright*

Our public relations work is a young activity, scarcely ten years old in the majority of our companies and still lacking entirely in some of them. If it has overstepped the bounds of right or decency in any case, we want to know about it more than any one else, so that we can correct the defects and raise the work to a still higher plane, but I do not believe this will prove to be true except perhaps in minor instances. I am confident that the commission will find what we already know to be true, that our public relations work is not only a legitimate activity but that it has benefited the public as much as if not more than it has benefited the industry.

Our public relations work has accomplished much in a short period of time in bringing about a sounder understanding and a pleasanter relationship between the public utilities and the public, and I believe that the public is better pleased and better served because of it. But there is still a great and an important work to be done, and I am confident that we, as an association and as individual companies, will go forward with it, undaunted.

territory that is served by adequate power systems.

In the wake of industrial progress has come increased commercial activity in the large and small communities of the state alike. New hotels, stores and other commercial establishments have been opened or are under construction in many small towns, showing that the decentralization of industry, effected by the widespread transmission of power, is affecting other social and commercial elements in the economic life of these communities.

In the territory of the Memphis Power & Light Company there has been a steady growth. In 1921 there were 426 industrial plants in Memphis, but in 1927 the number had increased to 606. Nashville, Knoxville, Bristol and other Tennessee cities record similar or greater industrial developments and have a notable reputation as progressive and rapidly growing cities with alert utilities serving them and helping them grow.

### Virginia Utilities Expanding

Virginia has been the scene of large utility consolidations in recent years. About Newport News developments have occurred whereby transmission interconnections are had with the Carolinas. Norfolk and Richmond have had a splendid growth and in the Shenandoah Valley and in the southwest small cities have been tied together to give extensive transmission systems, which in turn have brought about rapid industrial developments. While largely an agricultural state, Virginia has splendid assets for industrial developments on the coast and in the foothills of the Appalachian Mountains. A good roads program is under way and co-operative efforts are being made to develop the state in every possible manner.

Data on some typical Virginia utilities give a picture of the conditions which give promise of a prosperous future for the "Mother of Presidents." One of the new consolidations has been brought about by the Virginia Public Service Company.

*Growth of Tennessee Electric Power Company*

| | 1921 | 1927 |
|---|---|---|
| Kilowatt-hours generated | 342,948,926 | 651,397,468 |
| Installed generating capacity, kva | 137,490 | 265,050 |
| Miles of steel tower line, single circuit | 353.54 | 489.83 |
| Miles of wood-pole line, single circuit | 179.15 | 313.24 |
| Number of customers served | 45,464 | 91,259 |
| Population served | 440,000 | 500,000 |

In the year 1921, for the territory exclusive of Newport News, the generation was approximately 35,000,000 kw.-hr. In 1927 it exceeded 80,000,000 kw.-hr. The length of transmission lines in service at the close of 1927 was approximately 700 miles. In 1927 the number of customers was approximately 48,000 and the population of the towns served approximately 200,000.

The American Gas & Electric Company purchased some time ago the properties of the American Electric Power Company of Philadelphia, including the Roanoke Railway & Electric Company, the Lynchburg Traction & Light Company and the Consolidated Light & Power Company of Huntington, W. Va. About the same time it also acquired the old Appalachian Power Company of Bluefield, W. Va., and the Virginian Power Company of Charleston, W. Va. All of the electric lighting and power properties in these groups were merged into a new company, the Appalachian Electric Power Company, a Virginia corporation.

The following data cover operations in Virginia only:

| | 1921 | 1927 |
|---|---|---|
| Kilowatt-hours generated | 50,643,000 | 73,536,000 |
| Generating capacity, kilowatts | 14,000 | 20,500 |
| Miles single circuit transmission lines | 26 | 304 |
| Number customers | 17,000 | 26,500 |
| Estimated population served | 85,000 | 122,500 |

The small and overloaded local stations in this territory have been supplanted by an unlimited and dependable source of power supply received over 132-kv. transmission lines supplied by large modern and efficient generating plants, thereby affording an unlimited and dependable supply of electric power to the communities in this territory.

In southern West Virginia and eastern Kentucky rapid growth has been made since 1921. All the American Gas & Electric properties are connected together with high-voltage lines and interconnections of the American Gas & Electric system are had with the Carolina Power & Light Company at Danville, Va., with the Tennessee Public Service Company at Kingsport, Tenn., and through an interconnection with the Consolidation Coal Company the two Kentucky properties are tied together.

### Mine Load Predominates in Coal Regions

In the coal field areas electric power has been applied successfully to mining and some of the fields are completely electrified. Because of ample and low cost electric power mining companies can operate at any desirable location and many have increased production and lowered costs by using electrical mining equipments and methods.

In the Kanawha Valley near Charleston several large electrochemical and chemical plants have been built in recent years and afford the utility a splendid load. In some of these plants where process steam is used the industrial plants are interconnected to the utility system. Near Huntington the International Nickel Company has a very large plant and the future for these regions looks very bright to utility executives.

In the northern part of West Virginia the West Penn system gives an interconnection from the Pittsburgh area to eastern Pennsylvania. Water-power plants and fuel-burning stations are combined with transmission lines to give power in this large area, where coal and other resources are found in abundance. Diversified manufacturing is coming into being very rapidly in the West Penn territory.

### Still a Virgin Industrial Region

The South fairly hums with activity. Every utility is alert to build load and sends men to all parts of the country to sell industry the advantages of locating in its territory. Every barometer shows that the South is still a virgin region for commercial, agricultural and industrial growth. Yet it has gained national recognition for its possibilities at last and expects to capitalize on this recognition as soon as possible. In the front ranks of the aggressive leadership of the new South are found the group of energetic utility executives who are ready to reap the rewards deserved by those who have labored under the heart-breaking handicaps of past years. If Horace Greeley were alive today he would say, "Go South, young man." An electric spark has fired the South to build a new civilization.

*Latest addition to the chain of Bear River hydro-electric plants*

# Pioneering with Electricity

### Colorado, Utah and California characterized by hydro-electric development and high-voltage transmission. Customer ownership, irrigation pumping, oil field and mine electrification also are important

By Walter C. Heston
*Pacific Coast Editor*

DEVELOPMENT of large blocks of hydro-electric power in the high mountain regions of Colorado, Utah and California and transmission of this power over long distances at voltages ranging from 110,000 to 220,000 has meant conservation of water power and has brought about a degree of electrification exceeded by few sections of the country.

Remoteness of water powers from load centers early led to a solution of the engineering and operating problems incident to high-voltage transmission and a constant increase in transmission voltages has resulted. Today there is in operation in California more than a thousand miles of 220,000-volt lines. Five years of operation at 220 kv. by the Southern California Edison Company and the Pacific Gas & Electric Company has demonstrated the thorough practicability and dependability of high transmission voltage. Power from the Big Creek plants of the Edison company amounting to 258,000 kw. is transmitted to Los Angeles, a distance of 240 miles, over two 220-kv. lines and by the middle of the year 90,000 kw. from Big Creek No. 2-A plant will be added, at which time a third 220-kv. line will be placed in operation. Pit River power totaling 176,000 kw. is transmitted to the San Francisco Bay region by the Pacific Gas & Electric Company at similar voltage. The Great Western Power Company has 100 miles of 220-kv. line, at present operating at 165 kv., which interconnects its system with that of the San Joaquin Light & Power Corporation and will add an additional 80 miles of line to operate at 220 kv. to its system by the middle of the year.

In Utah the Utah Power & Light Company transmits 135,000 kw. from its hydro plants in northern Utah and southern Idaho to Salt Lake City at 130 kv., a distance of approximately 130 miles. The Public Service Company of Colorado has a 90-kv., 150-mile transmission line crossing the Continental Divide several times which delivers the output of the 15,000-kw. Shoshone plant to Denver. The 349-mile, 88-kv. line of the Southern Sierras Power Company between its Owens River plants and San Bernardino, Calif., is notable for its length, but cannot be considered as transmitting power from one extremity to the other.

With this brief mention of some of the most important transmission lines of the West and a study of the accompanying transmission map it will be evident that

Pacific Coast noted for high-voltage transmission and hydro development the populous sections of Colorado, Utah, Arizona and California are interlaced with a maze of transmission lines.

The policy of hydro-electric development and long-distance transmission followed by the utilities of this section over a long period of years has had a far-reaching effect upon development of the territory. It has enabled rural communities and practically every small city and town to enjoy full benefits of electric service and has been responsible for development of the "back country" upon which the larger cities must depend largely for their prosperity. With trunk transmission lines passing through the valleys it has been possible for the power companies to tap the lines at large load centers, from

# *California Enters Commercial Era*

*By A. F. Hockenbeamer*
*President Pacific Gas & Electric Company*

*A. F. Hockenbeamer*

ELECTRIC utilities of California entered the year 1928 with an ample supply of power for all needs; in fact, more kilowatt-hours are available today to serve the rapidly growing needs of the state than ever before in the history of the industry. On their financial side credit was never better. Their stocks were never in greater demand nor more widely owned. Their bonds never commanded a higher price in the financial markets. Money on good terms is available for whatever expansion may be ahead and for refinancing old obligations where they can be retired with advantage.

It is not expected, however, that on the whole building programs of utilities will equal those of the period of 1920 to 1925. This was a period of unusual construction activity to catch up with work necessarily postponed during the war, or stimulated by the unusual business expansion which followed the war. Utilities of California were back to normal by 1926 and the year just closed was likewise one of normal activity, of consolidation and co-ordination and of welding together existing properties. Several important mergers were effected in the interest of economy and efficiency. Within a comparatively few years the Pacific Gas & Electric Company has through absorption of fourteen smaller companies abolished the management staffs and management fees of these companies and saved a total sum for the benefit of its consumers approximating the total of the salaries at present paid to its own executive staff.

Economy and efficiency in operation was the goal of utilities in 1927 and the year closed with excellent records of operating economies by the larger utilities. There were many rate reductions during the year as a result of these economies, some of them amounting to 10 per cent or more. It is confidently anticipated that the recovery of the revenue lost by reason of these reductions will be greatly accelerated by the inducements for greater usage offered under the lower rates.

The light and power industry of California enters the year 1928 with the greatest commercial development program before it in its history. New business activities will be confined largely to increasing consumption of existing customers rather than extension into new territory. This follows from the fact that 92 per cent of all potential residential customers in the state are now served and that 62,000 California farms, or 45 per cent of the total, now enjoy the benefits of light and power service. My own company will spend at the annual rate of $1,000,000 for development of new business during 1928 and expects to add a load of 115,000 kw. That this program is proving highly successful is shown by the fact that during March 7,791 hp. of new business in household appliances alone was added to our lines. This represents the greatest increase in this class of business in any one month in the history of the company. Reports coming from other power companies of the state indicate similar success in their load-building efforts, and 1928 without doubt will be one of noteworthy commercial achievement.

The customer-ownership plan which originated in California still goes ahead apace. Today there are approximately 175,000 customer owners in the state, or an increase of 133 per cent over the number five years ago. This movement, originally intended to raise money for new construction, has also demonstrated its value in creating more friendly relations between the utility and its customers through making them partners in the business. The widespread ownership of stock under this plan is shown by the fact that there are only two stockholders of Pacific Gas & Electric stock that hold more than 1 per cent of the outstanding stock, and the aggregate holding of these two is only 6 per cent.

Presidential years have come to be looked upon as unsettled, but in so far as the utilities of California are concerned they apparently have no reason to fear such years. In fact, the last two Presidential years witnessed as large a growth as in other years and the Pacific Gas & Electric Company actually had a larger annual growth in these years than in any that preceded them.

The utilities of California face 1928 with conservative optimism; they enjoy good public relations, and confidently expect sound growth and development in the industry.

which distribution lines are extended, in turn, to industries and farms that otherwise could never have been reached.

### INTERCONNECTION

Had the situation which exists today with reference to the relative economy of steam versus hydro-electric generation existed ten to fifteen years ago much of this hydro-electric development and most of this transmission network might have come more slowly. However, under the program pursued not only have the benefits mentioned accrued but extensive interconnection of systems has resulted, until today all of the major utilities of California are interconnected. Several of the Arizona properties are linked and the system of the Utah Power & Light is tied in with that of the Idaho Power Company.

These interconnections fall into three general classes: Those for standby or emergency service only, those for straight wholesaling of power from one utility to another in one direction only and those for interchange of power between systems to enable the most economical over-all operation of the two. In the latter class the most notable interconnection anywhere in the West is that between the Great Western Power Company and the San Joaquin Light & Power Corporation. These two systems were connected by a 100-mile, 220-kv. line between Sacramento and Merced, Calif., two years ago, and since that time there has been a free interchange of power which has not only enabled utilization of available water supply to the best possible advantage but has added to reliability of service as well. During the spring of 1927, when there was an over-supply of power available from stream flow plants on the San Joaquin system, a 66,000-kw. plant of the Great Western Power Company on the Feather River was completely shut down for a period of more than a month and the water that would have been required for the plant was stored in Lake Almanor, a 1,300,000-acre-ft. storage reservoir, for use later in the season when power would be needed on the San Joaquin system. During this period the interconnecting line, which for the present is operating at 165 kv., carried as high as 75,000 kw.

As time goes on more interconnections of this type will be made as economies of a given situation dictate. Although, as previously stated, the power systems of California are practically all interconnected, these interconnections are largely for wholesaling of power in one direction only or for emergency purposes. In the latter category they have been invaluable on more than one occasion, notably that of the power shortage in 1924 due to an abnormally dry year. During the period of this shortage 12,000 kw. of steam power in the San Francisco Bay region was transferred through three systems a distance of approximately 500 miles and made available in the vicinity of Los Angeles to help relieve the situation where the shortage was most acute. Steam power from San Diego also was transmitted over interconnecting lines to the Los Angeles region.

With higher steam plant efficiencies, low price of fuels and lowering steam plant construction costs, steam electric generation is rapidly increasing, particularly in southern California and Colorado. The ratio of steam to total generating capacity (Table II) of the Southern California Edison Company has increased from 49.5 in 1922 to 75 in 1927. This company has embarked upon a steam plant construction program which will further increase this ratio as units are added in a third plant at Long Beach which ultimately will have a capacity of

### *Table II—System Data for Six California Power Companies Showing Growt*

720,000 kw. The first unit in this plant, which will have a capacity of 90,000 kw. and an economy of approximately 14,000 B.t.u. per kilowatt-hour, will be placed in operation in June of this year. Seven other units of similar capacity will be added as demands on the plant require.

The Great Western Power Company has under construction a steam plant in San Francisco which will have an initial capacity of 35,000 kw., the Pacific Gas & Electric Company is building a new steam plant in Oakland which will add 37,500 kva. of steam capacity to its system, the Los Angeles Gas & Electric Company is adding a second 43,750-kva. unit to its Seal Beach steam plant and the San Diego Consolidated Gas & Electric Company is adding a 25,000-kva. unit to its San Diego plant. Thus it will be seen that steam is destined to play a more and more important part in future power development in California.

### SYSTEM GROWTH

Several of the California utilities have shown phenomenal growth during the past five years, as will be seen from Table II. Of the six companies for which data are given the Los Angeles Gas & Electric Corporation has shown the greatest growth with an increase in generating capacity of 158 per cent and in output of 166 per cent, and this is in spite of competition with the Los Angeles municipal system. The Southern California Edison Company has shown the remarkable increase in generating capacity of 110 per cent and in generation of 114 per cent, or an increase of more than 20 per cent a year over the post five-year period. In the intermountain region—a section growing less rapidly than California in population and industrial development—the Utah Power & Light Company has shown an increase in generating capacity of 56 per cent and in output of 44 per cent, or approximately 10 per cent per year.

purchase of power.

To provide for rapidly increasing demands for electric service the six California utility systems given in Table II required an increase in generating capacity of 58 per cent, or 630,000 kw., during the past five years, or an average of 116,000 kw. per year. At an average of $150 per kilowatt for both steam and hydro this means that $17,400,000 of new capital is required each year for plant investment alone, and assuming that $400 per kilowatt is required for transmission and distribution, an additional capital outlay of $46,400,000 is needed. Allowing for several smaller companies not included, approximately $75,000,000 of new money all told is required each year.

### CUSTOMER OWNERSHIP

Approximately $15,000,000 of this new money is raised each year through the sale of securities to customers in the territories served. The origination of the customer-ownership idea is credited to A. F. Hockenbeamer, now president of the Pacific Gas & Electric Company, who in 1914 conceived the idea of junior financing through direct sale of stock to the company's patrons. The movement spread rapidly after 1917, when it was taken up by the Southern California Edison Company, and today there are approximately 175,000 individual stockholders among the customers served by California utilities, holding a quarter of a billion dollars of utility securities.

The number of customer owners of utilities in the Southwest has grown rapidly. During the past five-year period there was an increase of 132 per cent in the number of stockholders. The Southern California Edison Company has by far the greatest number of customer owners of any Western utility, having at the close of the year 1927 102,000 customer owners. By May 1, 1928, this number had been increased to 117,000.

At its inception the customer-ownership idea had as its primary object the raising of money for capital expenditures at a time when money was difficult to obtain.

That the plan did serve this purpose is evident from the widespread sale of stock. However, during the post-war period, when the money market had eased up and public confidence in the light and power industry had made it possible to secure capital in large amounts and at reasonable rates, the customer-ownership movement began to take on a different aspect, that of improving public relations in individual communities served. Today this is the primary object of nearly all customer-ownership activities. Without doubt the widespread and diversified holdings of utility securities has been responsible for a degree of public confidence in the utilities that serve them that could not have been brought about in any other way. Without doubt, too, it has been instrumental in the defeat of many pernicious public-ownership schemes proposed, particularly the thrice defeated water and power act of California.

### Agricultural Development

Irrigation pumping as a basic agricultural load has brought about widespread use of electricity on the farm in the great valleys of California, the region around Phœnix, Ariz., and in the great Salt Lake basin of Utah. Probably the first electric motor installation for irrigation pumping was made near Visalia, Calif., in 1899 by A. G. Wishon, now president of the San Joaquin Light & Power Corporation. Mr. Wishon had the vision to see the possibilities of developing a profitable pumping load and building a central-station load in a territory where there was little central station business in sight by fostering agricultural development, which would in turn bring more people and industries for his company to serve. The original rate made for pumping in the San Joaquin Valley was $50 a horsepower year and through a liberal extension policy the load has grown until today 31 per cent of the company's gross revenue and 31.4 per cent of its energy sales come from agricultural business. More than 12,000 pumping plants having a connected load of 136,178 hp., or 35 per cent of the motor load of the system, are now served. Important agricultural and pumping loads also are served by the Pacific Gas & Electric Company, Great Western Power Company and Southern California Edison Company.

The extent to which California farms are electrified is shown by a recent survey made by the California Committee on the Relation of Electricity to Agriculture. This survey shows that on the basis of 128,000 farms in California, as indicated by the 1920 census, 51,000 farms, or 40 per cent, were receiving electric service in 1925, the latest year for which figures are available. These farms had a connected power load of 635,913 hp. and consumed for power only 712,947,487 kw.-hr., which produced a gross revenue of $11,010,694. The average connected power load per customer was 15.77 hp., the average annual consumption 17,652 kw.-hr., average annual revenue $273.08 and the average rate paid per kilowatt-hour 1.54 cents. The large pumping load served by California power companies has been responsible for high system load factors and in most cases summer instead of winter peaks.

### Mine and Oil Field Electrification

Extensive coal and mineral mining operations in Colorado, Utah, New Mexico, Arizona and Nevada are practically all carried on with electric power. Probably not more than half of the power utilized is supplied by central stations due to the remoteness of the mines from transmission lines. The most notable case of utilization of central station power in mining operations in this region is that of the Utah Copper Company, near Salt Lake City, where the Utah Power & Light Company supplies all of the electrical energy used on the property. This and other mining loads served by the Utah Power & Light Company used 429,000,000 kw.-hr. in 1927, which was 65 per cent of the company's total electric energy sales. The high load factor of the mining load was largely responsible for a system load factor of 75.5 per cent for the year 1927.

In the large copper mines of Arizona, at Jerome, Globe, Miami, Bisbee, Ajo and the smelting center at Douglas, practically no central-station power is utilized, although mining, hoisting and refining are largely done electrically. As the territory develops and transmission lines are extended central-station power will be utilized to a greater extent to supply requirements over and above the capacity of the present isolated plants. Already the lines of the Salt River Valley Water Users' Association are connected to the system of the Inspiration Copper Mining Company at Inspiration and a line is now under construction which will tie in the Arizona Power Company with the plant of the United Verde Copper Company at Clarkdale.

One of the pioneer pumping installations in the oil fields of California was that made at Coalinga in 1909 on the system of the San Joaquin Light & Power Corporation. In 1913 the first electric drilling operation took place in the same territory. A great deal of effort has been devoted by the San Joaquin Light & Power Corporation to developing the oil field load and the success of this effort is evident from the fact that the company now serves an oil field load of 25,000 kw. and during 1927 its energy sales to this class of business amounted to 73,706,532 kw.-hr., or 13 per cent of its total energy sales. Oil fields of southern California also are extensively electrified, some of them completely and some only partially. Much of the pumping is still done with natural gas engines, but with the increasing market and rising price of natural gas, oil-producing companies are finding it more economical to sell their gas and utilize electric power for pumping. The economies of electric drilling as compared with steam or gas are so great as practically to preclude the latter forms of power in future drilling operations.

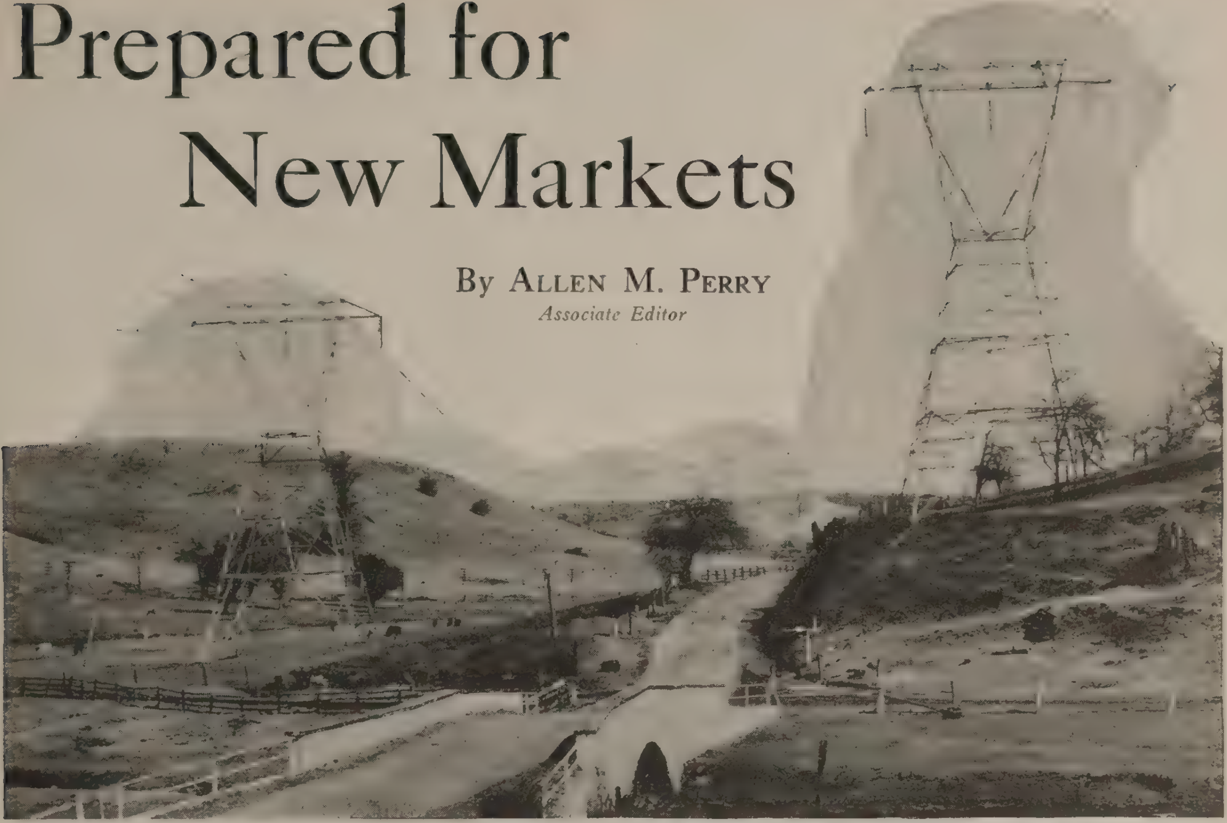
### Domestic Load Building

In their efforts to secure business the power companies of the Southwest have not concentrated on domestic load building to the same extent as their neighbors in the Northwest. As far as coverage of their territory is concerned the Utah Power & Light Company and the utilities of California have done a particularly good job. The Utah company serves 98 per cent of the available domestic customers in its territory, while 92 per cent of all potential residential customers in the state of California are served by the electric light and power companies.

Until recently few companies had intensively cultivated the domestic field. Within the past two years, however, there has been a general commercial awakening, and with only two or three exceptions every power company in Colorado, Utah, New Mexico, Arizona, Nevada and California is now engaged in an intensive commercial development program, with particular emphasis on the domestic customer. Already these effects are showing promising results and the next five-year period will see an increase of at least 50 per cent in domestic consumption.

# Prepared for New Markets

### By ALLEN M. PERRY
*Associate Editor*



Dense population and proximity of good-sized cities and towns to one another in the Middle Atlantic States, together with their highly industrialized territory, have brought interconnection and development on a large scale, chief interest now centering in maintenance of service and development of future markets

WITHIN the three Middle Atlantic States of New York, New Jersey and Pennsylvania there are more than 400 cities having a population of 5,000 or more, 233 with 10,000 or more and 44 with 50,000 inhabitants or more. With such nuclei for load centers and state populations averaging no lower than 207 persons per square mile in Pennsylvania and as high as 426 per square mile in New Jersey, there has not been the economic difficulty, which some sections have experienced, in spreading out systems, interconnecting and consolidating.

Such populous centers as New York, Philadelphia, Pittsburgh, Buffalo and Newark, with their concentrated domestic populations and commercial and industrial loads, have exacted very reliable service and called for the building of large, efficient generating stations, large load-center substations and high-density distribution systems.

Superposed over and interposed between these aggregations of human beings who make up the domestic load and justify commercial loads is a tremendous industrial market composed in 1925 of approximately 60,000 establishments using 10,000,000 hp. to turn out yearly products valued at close to $20,000,000,000. There are more than 33,000 of these establishments in New York State and more than 17,000 in Pennsylvania.

Delaware and Maryland are not so populated or industrialized, having jointly only ten cities with populations of 5,000 or more and 3,603 industrial establishments. Nevertheless, these states generated 583 and 437 kw.-hr. per capita respectively in 1927, compared with 1,025 kw.-hr. and 795 kw.-hr. for New York and Pennsylvania.

Faced with these opportunities for business and the economic possibilities of extending their systems, electric utilities in this territory early stimulated extensive utilization of purchased energy. When the World War broke out and this territory became the scene of unprecedented industrial and commercial activity many industries changed to purchased power. Demands were made on utilities that severely taxed their capacity for service and probably urged interconnections forward as much as anything.

Relief came during the adjustment period after the armistice and for several years utilities rehabilitated plants which had operated with virtually no maintenance for several years and installed much needed new generating capacity. The high unit costs at which these additional generating facilities had to be installed urged commercial departments to greater efforts. The extended taste of purchased power, the vigorous efforts to acquire new business and returning prosperity of a different order eventually called for more generating equipment and interconnections. Consolidations of the smaller properties into the larger ones became more numerous, and holding companies sought to increase their financial credit and hence their capacity for carrying on developments by extending and diversifying their holdings. Finally, the

12

plentiful money market of the last few years arrived that has permitted refinancing as well as raising of new capital at lower rates.

Despite the existence of Niagara Falls power in this territory and the recent completion of the Conowingo and Wallenpaupack hydro developments, steam power still predominates in the proportion of 68 to 32. Among the important steam stations built in the last six years were East River, Kearny, Hudson Avenue, Charles R. Huntley, Gould Street, Binghamton, Richmond, Delaware, Deepwater, Whippany, Pine Grove, Shippingport and Saxton.

Interconnection of adjacent systems and plants has grown apace, as the accompanying transmission maps and table of inter-system ties indicate. Networks have been developed that tie together practically every system within the states considered and even connect the group with outside territories that are just as extensively interconnected. For example, there is a tie with the New England Power system on the northeast through the Mohawk-Hudson Power system. On the northwest the Buffalo, Niagara & Eastern Corporation is tied in with the Hydro-Electric Power Commission of Ontario. On the west the West Penn Power Company is interconnected with the Ohio Power Company.

The inter-system interconnections within this territory, while requiring that the systems operate in parallel, do not permit bulk transmission of energy from one end of the interconnected network to the other. However, nonadjacent systems have been able to exchange energy by load displacement in the intervening systems.

A few examples of heavy ties between adjacent systems do exist like those between the Hydro-Electric Power Commission of Ontario and the Buffalo, Niagara & Eastern Corporation, or the more recent 220-kv. tie connecting the Pennsylvania Power & Light Company, the Philadelphia Electric Company and the Public Service Electric & Gas Company. But even these ties exist chiefly for adjacent system interchange.

Interconnection between stations of the same system or affiliated companies range from loose ties (having capacity sufficient to offset loss of local reserve) to trunkline ties the equivalent of a station bus. Probably the outstanding example of the latter type is the 132-kv. trunk between the Public Service Electric & Gas Company's Marion, Kearny and Essex stations, all within a stretch of about 3 miles. While ranking large in capacity, the ties between Canada, Niagara Falls and Buffalo and between the New York stations could hardly be considered as solid ties as the one in New Jersey. Brooklyn affords an example of large generating units paralleled only through substations, while Baltimore does likewise with its two generating stations.

Backbone transmission lines of the order of 110 kv. are evident in most of the Eastern systems that serve long narrow strips of territory like the Niagara, Lockport & Ontario Company and the Mohawk-Hudson Power Corporation. But they serve chiefly as transfer buses between separated generating stations and make power available where there may be inadequacies or loss of reserve. For such service multiple circuits are employed, in some cases over separate right-of-way.

Loop transmission lines of a similar order of voltage are used or are being favored by companies wherever their territory is adaptable to this method. They are also used around the outskirts of cities to provide reliable service to industries, raise the limits to loads which can be taken on and avoid radial feeds from generating stations to these industries as well as outlying residential sections.

Loops exist around the Buffalo-Niagara district and Pittsburgh. They have been started around the north of

## *Some Major Interconnections in Middle Atlantic States*

This shows that directly or indirectly all of the companies listed (with exceptions of Nos. 8 and 10), are connected with each other and with New England, Canada and Ohio, and therefore operate in parallel, although interconnections are used only to exchange power with adjacent systems.

*Tied with Hydro Electric Power Commission of Ontario.
†Tied with Ohio Power Company.
‡Tied with New England Power.
¶Tied with Potomac Public Service & Keystone Power Corp.

Baltimore, the congested industrial district of New Jersey and are being considered on the eastern end of the Mohawk-Hudson system. The Penn Central Light & Power Company is an example of a company serving separated industrials through looped circuits. At points around the Duquesne loop as well as the New Jersey loop are tap substations from which lines run to load-center substations within the loop.

Interconnection arose as an opportunity for making the best use of investment in generating plants in adjacent districts. But it was soon observed that the most flexible utilization of interconnections could not be obtained under separate ownerships, as complicated contractual agreements and differing engineering practices often hampered operations and parties to the interconnections were chiefly interested in how they could benefit individually rather than in how the best use could be made of the entire interconnected capacity. As a consequence, consolidations of adjacent properties under the same financial ownership sprang up, giving a community of interest and purpose.

In such consolidations were also seen the opportunity to enhance financial credit standing, make purchases in bulk, avoid widely differing engineering and commercial practices, provide engineering and commercial staffs which smaller components could not support alone, simplify accounting and reports to government and commissions, reduce total overhead administration expense, smooth out demands on construction forces, etc.

In New York State the Mohawk-Hudson Power Corporation is well on the road to co-ordinating diverse interests and practices from Albany north and west through Utica and Syracuse. The Buffalo, Niagara & Eastern Corporation has well in hand the unification of service in the northwest part of the state from Buffalo and Niagara Falls east along the southern shore of Lake Ontario. A billion dollar merger involving the Brooklyn Edison Company and Consolidated Gas group of properties in New York City has at last been ratified.

The major changes in Pennsylvania have included bringing the Philadelphia Electric into one United Gas Improvement family, the Duquesne Light Company into the Byllesby group and the Penn Central Light & Power Company under Insull interests. The West Penn Power Company is developing and expanding service to the multiplicity of towns surrounding the Duquesne Light territory, which runs northwest and southeast through Pittsburgh.

The Consolidated Gas, Electric Light & Power Company, serving Baltimore and surrounding territory, still remains independent, although it has been rumored that a large holding company is seeking control.

As a recent example of what consolidation can do, the Mohawk-Hudson Power Corporation is typical. Only a few years ago the 27 or 28 plants that now constitute this system were divided among five major companies and a number of smaller properties. Water-power rights and different frequencies and voltages hindered the best use of these properties even after attempts at interconnection. Now the parent company, through providing a mutual financial interest, is fast removing barriers to unified operation, co-ordinating operation for best system results, eliminating diverse engineering practices where feasible, harmonizing water-power utilization with outside interests and avoiding sharp differences in handling customers of the component companies. This company is still in the transitory stage.

Because of the previous affiliations of the Niagara Falls Power Company, Buffalo General Electric Company, Niagara, Lockport & Ontario Company and other subsidiaries, the Buffalo, Niagara & Eastern Company, which was formed as a holding company just a few years ago, has been able to make very rapid strides toward simplification of its corporate and financial structures. Already it has exchanged holding company common stock for practically all of the outstanding common stock of its

subsidiaries, and before the year closes it is expected that all the subsidiaries' outstanding preferred stock will be replaced by holding company preferred stock and the bonded indebtedness of the subsidiaries assumed by the holding company. Thus the financial structure will be greatly simplified and the Buffalo, Niagara & Eastern Corporation can be made a true operating company and not merely a holding company.

### Looking for New Markets

At no time in the past has there been available so much money at such low rates as now to develop business facilities. Pushed by this incentive and the need of putting excess generating capacity to work earning money, the utilities' major thoughts now are on where to seek and how to develop additional business. All companies are interested in maintaining domestic customers' revenue at such a proportion of the total that it will continue to stabilize gross revenue during industrial depressions. Since municipal services and commercial and office building lighting do not vary appreciably with business conditions, these too are considered attractive stabilizers. Some companies have very diversified load, but wherever any one or a few industries dominate the industrial load attempts are being made to offset these loads by distinctly different loads, either through attraction of new industries or concentration of sales effort on diversified industries. A few utilities are looking to existing and additional interconnections as the chief means of disposing of their product.

One field for development which is beckoning is electric heat. Every place that coal, oil or gas is now used for some process affords a potential market. How extensive each local market is, what classes of applications are most attractive and where specifically to concentrate attention are questions that will have to be answered by each utility surveying its customers' uses of heat as a few companies are doing and others will eventually find it profitable to do. Baltimore and Pittsburgh have just completed detailed surveys.

Applications of electricity to chemical processes have hardly been touched, said one utility man, because neither power salesmen nor works managers of chemical industries have given sufficient study to the existing practical applications of electrochemistry.

Users of process steam and industries utilizing byproducts to produce their own power constitute the major remaining potential market for purchased power outside of that which comes from population growth. This market has been difficult to enter chiefly because industrialists or their consultants do not account for all items charge-

*Penn Central Light & Power loop serves scattered industries* able to power production as rigorously as utilities do. If industrialists can be induced in some way to give more attention to proper accounting for production costs one of the greatest obstacles to proving the economics of purchased power to industrial executives will be broken down.

Meanwhile there are two approaches to this market that are being tried with varying degrees of success. To win process-steam users over to purchased power, the Rochester utility just recently built a steam-heating plant in the load center of about twelve large isolated-plant-operated industries and is already serving one of them with steam and electricity. In reducing the steam pressure for steam supply it passes the steam through turbogenerators floated on the utility system. As time passes it hopes to convince the other surrounding process-steam users that they can afford to do likewise. In eastern Pennsylvania it has been found feasible for one industry to locate near the utility's generating station from which it secures both steam for process operations and electric power for other operations, but many utilities point out that such a location is seldom convenient for industrial plants.

Interchanging power with large industrial private plants on the same basis as with another utility is being tried with varying degrees of success with the understanding that the industrials will purchase all increases in power demand and the hope that a taste of purchased power will induce them eventually to replace obsolete isolated plant equipment by purchased power. Industrial interchange of power, where it has been practical, has not brought the benefits of interconnection with other utilities because the surplus power from industrials is usually available to utilities when it is not needed, but

# *Do We Want Applause Cards?*

*By Frank L. Dame*
*President the North American Company*

FOR a time applause cards were in vogue in the radio field. Tons of mail came in response to the familiar request: "If you have enjoyed this program write to So-and-so Company direct, or to the station to which you are listening." Today these cards have largely disappeared from radio. The movies, in a limited way, are carrying the idea a step further by asking for opinions of some films.

In most lines of business the applause card, in one form or another, has been sought. Is this really what is wanted? Is not constructive criticism a better guide for future plans for improvement?

My conclusion several years ago was that our company did not want applause cards, but on the contrary wanted criticism that was constructive. As a result we inaugurated a policy of sending letters to every person whose name disappeared from our stockholders' list asking frank expressions as to the reason for the disposal of the shares. The replies average more than 55 per cent of our inquiries, and all of them are tabulated and studied. I am glad to say that with few exceptions we have found no serious complaints regarding our policies and that cases of complaint have been generally removed by explanations of stockholders' previous misunderstandings.

This is a fair illustration of the value of constructive criticism as against mere applause. Criticism makes more noise than applause; it has greater news value because it is not so commonplace. This is quite apparent, and is very well illustrated, in the proceedings of the Federal Trade Commission in its examination of the public utility industry.

A year ago I publicly expressed my views on some of the conditions in the industry that merited criticism, and later events showed that these conditions were its disturbing elements. It was inevitable that such conditions should lead to criticism, which, unfortunately, has been more destructive than constructive. Consequently the emphasis has been heavy upon the mistakes, minor and major, which have been revealed. And the noise of this criticism—that which is justified and that which is not—renders quite inaudible the public approval of the policies and practices of the larger part of the industry.

*Frank L. Dame*

Criticism, to be valuable, must be constructive. I welcome that kind, and would rather have it than tons of applause cards. I join in the criticism of improper conditions and practices in the industry on the ground that their correction will benefit the public, the industry and its millions of investors.

A case in point has been brought forward by the secretary of the National Educational Association. He indorsed the industry's action in preparing information of value for the schools as a work of education, but he condemned the improper inclusion of propaganda against public ownership. And he asked the association to consider at its Minneapolis meeting, June 30, a report on the extent to which agencies other than public utilities "have imposed on teachers in the schools." To me this is constructive criticism, and it embraces all efforts toward propaganda, against the public utility industry and in favor of it.

We do not want applause cards, but constructive criticism.

the arrangement has proved advantageous in several places as a means of opening new markets.

What is known as a "business incubator" has been started in Rochester for the purpose of stimulating new industries or new processes. Electricity in all forms, steam at various pressures and superheats, gas and a variety of chemicals are made available in a loft building where a large number of industries can experiment with new processes at less expense than if they provided all their own facilities. In Baltimore industries which are too small to build their own quarters and equip for electric, steam and gas services have had the opportunity for twelve years of renting industrial quarters provided with these services. Where found worthy they have been able to secure financial aid until they are able to proceed on their own resources.

Quite a tendency is now prevalent for utilities to co-operate with their local chambers of commerce in attracting new industries into their territories. On the other hand, one state chamber of commerce is discouraging such activity, as it declares that national records prove that there are seldom economic justifications for such changes. Commenting on this subject, one utility says it never seeks outside industries unless they show a determined intention to move or decentralize their plants and then active efforts are made to interest them in local conditions. Decentralization of industries to reduce distribution costs is accounting for many of the changes in industrial plant locations, although cost of power has influenced congregation of electrochemical and metallurgical industries at Niagara Falls.

In western Pennsylvania it is declared that the most favorable conditions for progress cannot exist until the bituminous and anthracite mine operators adjust their difficulties. Subnormal production in some steel mills, copper rolling and drawing plants and metal-working factories is affecting some utilities which depend to a large extent on these industries for their power load.

For increased commercial load as distinguished from industrial, utilities are looking to selling purchased power to new buildings before they sink their money into private plants, to co-operating with architects and building owners in laying out the most effective lighting and to improving store and show-window lighting. Some utilities feel that through installation of the best street lighting, inadequate show window and store lighting can be most effectively demonstrated. Commercial refrigeration has been found a very attractive load builder in some communities. The potential market for this air conditioning has developed wherever department stores, theaters and other public gathering places have been shown the beneficial effect of artificially cooling interiors.

### INDUCEMENT RATES AND MERCHANDISING

Because domestic customers utilize such a notoriously low percentage of the investment required to serve them and require such high unit operating expenses for testing and reading of meters, accounting, billing, etc., and also because their aggregate revenue fluctuates so little with economic conditions, utilities as a whole are showing unusual interest in developing their usage of energy. Not many years ago few companies had inducement rates to stimulate more extensive usage, but a large number of utilities in the Middle Atlantic States now have them or are introducing them. With such rates customers can be impressed with the fact that any additional usage they make of electricity can be had at very small expense. Where the companies have backed up these rates with sales effort and do not require their domestic customers to take too many kilowatt-hours at the top step before they can take advantage of the low step, some really remarkable increases in customer consumption have been made. But the surprising situation in some local-

---

# *Customer Ownership on Increase*

*By* ***P. G. Gossler***
*Chairman of the Board*
*Columbia Gas & Electric Company*

*P. G. Gossler*

IT IS gratifying to note that the sale of stocks and other securities by electric light and power companies to their customers during the past year have exceeded the record of any previous year. This is particularly gratifying because of the fact that market conditions during the past year have been unusually favorable, through low interest rates, for selling of long-term bonds for raising new capital, and also for the refunding of outstanding issues of bonds or stocks to meet maturities, or where outstanding securities may be called. As the sale of securities to customers is, for the greater part, in preferred stocks representing junior securities, it would be expected that the proportion of such junior financing would not be as large in years where a very strong bond market prevails. It is most significant, therefore, that customer-ownership shares sold during 1927, as reported, aggregated 3,484,000 shares, which is an increase of almost 30 per cent over the record in 1926. Also, the number of electric companies that have issued such stocks has increased during the year to 242, compared with 228 so reporting last year. The number of new stockholders added last year was 235,674, which brings the total to date to 1,668,000 stockholders having purchased an aggregate of 16,622,000 shares.

ities is that the increased consumption has not increased the average revenue per customer. On one system where the average domestic consumption is over 700 kw.-hr. a year the revenue is only $25. Furthermore, when inducement rates are first introduced it has taken as much as one and one-half years to bring the domestic revenue up to what it was on the old flat rate. . So utilities, while recognizing the wholesome effect of such rates on public relations, are chiefly concerned with finding applications which will be attractive to customers and at the same time build up the revenue per customer.

Some difficulty has been experienced in introducing inducement rates without taking too big a loss in revenues or raising the small customers' bills. If the inducement rate is formed to keep the small customers' bills the same the revenue loss from the domestic customers as a whole is considerable. And if the rate structures are made so that this loss is minimized, the antagonism of small consumers whose bills are raised is aroused. As a result some utilities have expressed the opinion that the time to institute an inducement rate is when surplus earnings are expected.

Along with this tendency to give domestic customers inducement rates has therefore come an increased incentive to concentrate on merchandising. There are still many schools of thought, ranging from merchandising purely for merchandise profit without regard to load building to merchandising chiefly for load building.

There has been a widespread improvement of electric shop layouts for the convenience of customers even in small towns. Greater attention is being given to simplifying applications for service, securing duplicate bills, adjusting complaints and paying bills.

More companies are adopting practices that improve public relations and not merely talking about them. Among some practices which have been adopted are: Removing sharp differences in practices brought about by mergers of adjacent companies; discontinuance of signed applications and deposits except where credit is questionable; leaving service connected in empty homes; following up service connection orders; minimizing public inconvenience from construction work; simplifying payment of bills; expediting correct connection of incoming telephone calls; remedying causes of radio interference; training of employees in courtesy by the legal-case method; committees formed of department heads to adjust practices that cause public irritation, and supervision of telephone complaint adjustments.

## *Some Actual Budgets for 1928*

The total of the expenditures here listed, excluding duplications and Ontario Hydro, is $301,555,770. Of that amount $295,655,000 can be associated with installations having a combined rating on Jan. 1, 1928, of 8,516,115 kw., according to the best available records. The total for the United States at that time may be taken at 25,760,000 kw., again using the most recent figures available.

| Company | Total, 1928 | Steam | Hydro | Transmission | Distribution | Substation | Miscellaneous |
|---|---|---|---|---|---|---|---|
| 1. Alabama Power | H $15,000,000 | | | | | | |

# Service in Rural Areas

Prairie states are interconnecting many independent properties and gradually consolidating. Load concentrations are chiefly around cities. Hydro powers have been developed to a high degree. Rural service active

### By Frank R. Innes

*Delhi station Interstate Power Company*

THE West North Central region, comprising Wisconsin, Minnesota, the Dakotas, Nebraska and Iowa, is predominant agricultural, including, as it does, the states which lead in the production of wheat, corn, barley and oats. Mineral resources exist in three of the states, but principally in Minnesota. A large share of the country's iron-ore production comes from the Mesaba Range in northern Minnesota. South Dakota contributes about 10 per cent of the national production of gold and, with its sister state to the north, has unexploited mineral resources, including petroleum.

Except in the southeastern part of Wisconsin, where a great and diversified manufacturing activity exists, the principal industries of the group are grain milling and meat packing. Milling centers largely in and around Minneapolis, while packing is chiefly concentrated at Omaha. However, these two industries are widely scattered over these states. In Wisconsin, and to a lesser degree in Minnesota, lumbering is an important activity, there being in these two states one of the few remaining stands of Northern pine. On account of the introduction of modern methods of timber production, these timber stands will remain in the productive state for many years to come.

Dairying and the manufacture of dairy products are important in the eastern part of this area, but particularly so in Wisconsin, which is rapidly earning a wide reputation for cheese production.

Population in this territory has increased nearly 6 per cent since 1920, the greatest increase having occurred in Minnesota and Wisconsin, the former adding nearly one-third and the other more than a quarter of a million.

Therefore there is not much to indicate any slacking up of electrical development in this region. And this evidence is not controverted by the facts concerning that development.

Some of the major electric utility interests concerned in these states are: The Electric Bond & Share Company, Standard Gas & Electric Company, Middle West Utilities Company, Utilities Power & Light Corporation, United Light & Power Company, American Gas & Electric Company, North American Light & Power Company, North American Company, American Light & Traction Company, United Gas Improvement Company and Engineers Public Service Company.

The Lakeside station of the Milwaukee Electric Railway & Light Company was the first large generating station to burn pulverized fuel. It was a pioneer in the use of high-pressure steam and the first large-scale studies of coal distillation in America were carried on there.

Privately operated utilities have made great progress

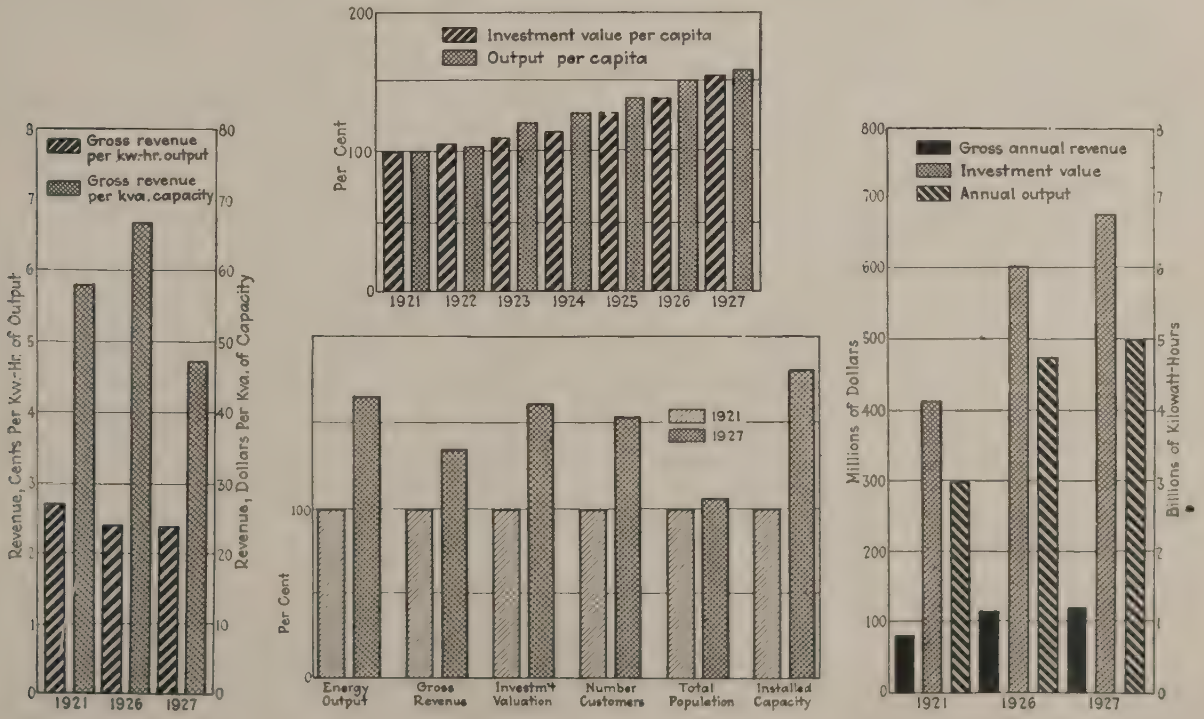
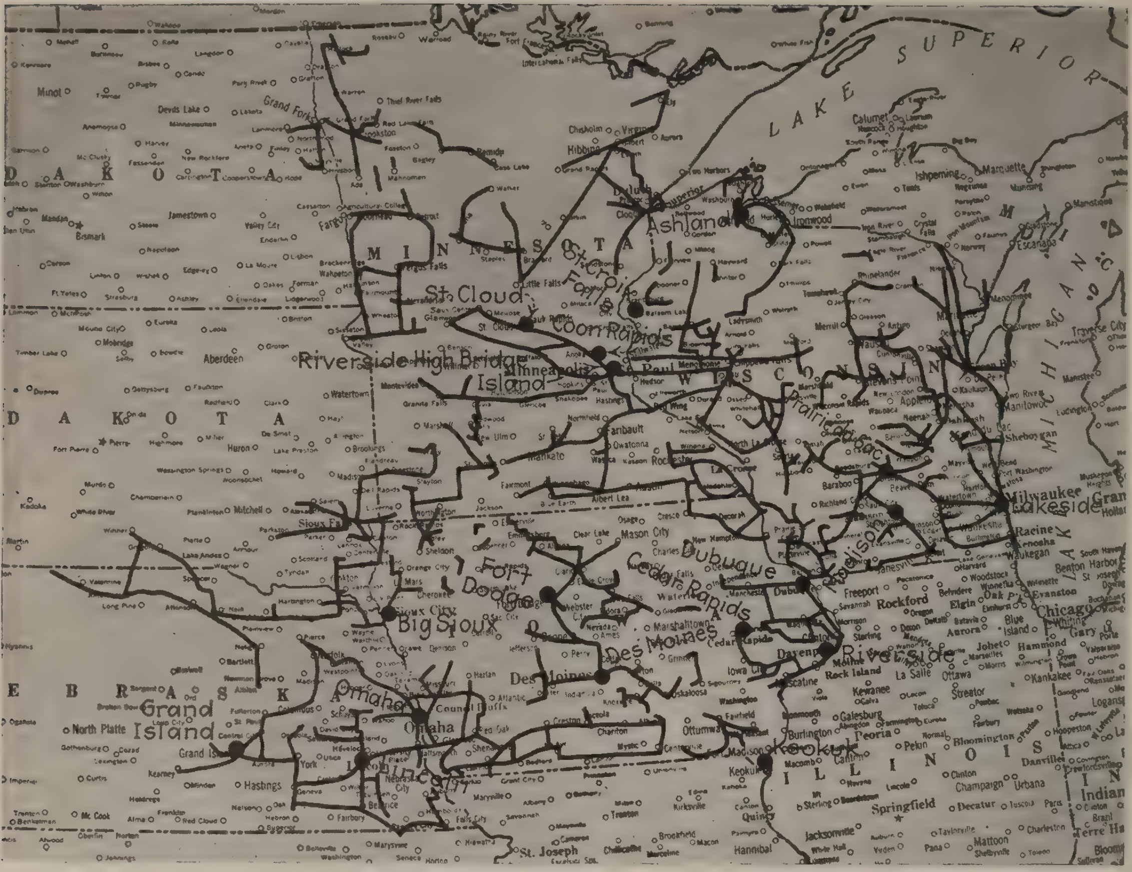
against the local independent plant idea, whether it is expressed in municipal or private ownership. To the evidence presented by the published analysis of electricity rates before and after absorption of 62 Iowa municipal undertakings by Arthur H. Ford of Iowa City there may be added the following information furnished by F. R. Moulton of the Utilities Power & Light Corporation: "An examination of costs to the consumers served by local utilities in towns of the same population classes and in the same territory as those on the system of the Interstate Power Company shows that the privately owned central station saved $1,443,351.70 for its customers in 1927, this sum being the difference between what they actually paid and what they would have paid if they had been served from an independent plant and not from an interconnected system. In the last seven municipal plants taken over by the company the saving in electricity costs to consumers was 15.6 per cent for lighting service and 16.1 per cent for power. These figures take no account of the payment of taxes by the privately owned utility, whereas the municipal plants paid no taxes. Correcting them for this factor makes the actual savings 18.6 per cent for light and 19.4 per cent for power. That these savings will increase as time goes on is indicated by the fact that in 1927 voluntary rate reductions by the Interstate Power Company made a total reduction in customers' bills of $119,691.54."

In spite of the numerous municipal utilities in these states, or perhaps because of them, consolidation of electric properties into connected operating groups has made much progress. This progress would probably have been more rapid at first had it not been for the resistance interposed by independent utilities having a long history of prosperity and public regard, which made them reluctant to relinquish independence for the unproved advantages of consolidation. But this phase is now in the past. However, on account of the militant independence of the average municipal undertaking and the let-well-enough-alone attitude of some of the privately owned properties, base-load plants and unit planned systems are not so characteristic of these states as they are of the West and South. Instead, the systems are built up around the already established generating stations of the cities. In many cases these stations have taken on more than the local responsibility with which they started and assumed the character of base-load stations.



*North Central energy output has grown much faster than population in six years*



*Interconnections, hydro and steam plants have thrived in North Central States*

Concentration of power around important cities is not so conspicuous in Minnesota and Wisconsin, where the development of water powers has spread the systems out more. The plants of the Middle West Utilities subsidiaries on the Wisconsin River, of the Northern States Power Company on the Mississippi and St. Croix Rivers and other developments in northern Wisconsin and northeastern Minnesota have either been recently built or expanded from earlier installations at the same sites. In these two states a great many water powers were wholly or partially applied to milling long before the present era of electric power. As electric power came into use numbers of these were adapted to generation for local supply. In not a few cases it has been found advisable, from considerations of economy or policy, or both, to retain these water powers for continuous use or for stand-by when interconnected systems grew up. As a result the hydro powers of these states have been developed to a higher degree than elsewhere.

Practically the only fuel used for steam generation of electricity in this region is coal, the greater part of which is brought in from Illinois and Kentucky fields. However, in Iowa and the Dakotas, also in Minnesota in lesser quantity, there are large deposits of low-grade bituminous coals and lignite. Iowa is much interested in the utilization of its local coals and a number of generating stations in the state are experimenting with burning these fuels. Not much has been done in exploiting lignite because the deposits are far from centers of power use and the national coal resources will have to be considerably more depleted than now to justify adding a freight charge to the cost of lignite.

Long-distance, high-voltage transmission of large blocks of power is not common in the north central region. However, it is used by a few utilities that operate major hydro-electric stations. The greater part of the systems in these states might be referred to as high-voltage distribution. The reason for this is that most of the systems have spread out from established nuclei by progressive extension of lines. Load concentrations at the end of long lines are infrequent; the more common condition is that of load distribution throughout the whole length of lines.

Interconnection, as a means for staggering investments in generating capacity between contiguous systems, is quite a common practice. The interconnections serve chiefly as means of exchanging reserve capacity rather than for the continuous transmission of large quantities of energy. A typical example of this class of interconnection is the 132-kv. tie between the Milwaukee Electric Railway & Light Company and the Public Service Company of Northern Illinois. This tie makes available to the systems of southeastern Wisconsin a certain part of the reserve capacity of the Chicago power pool and vice versa, both areas profiting in terms of system reserve investment even if no power were ever transmitted either way on the line.

In the western and more thinly populated part of this region the building of transmission lines is almost a direct measure of the taking over of municipal utilities and of

# *Consolidations Increase in Prairie States*

### *By Don M. Sterns*

*Vice-President Iowa Public Service Company*

ELECTRIC companies in the Middle West Division of the National Electric Light Association, comprising the states of Iowa, Nebraska, Kansas and Missouri, serve 1,617,200 customers in a population of 9,055,065. Figuring four and a half people to a family, more than seven out of nine people have electric service.

A steady and gratifying increase in production and consumption of electric energy, more and better construction of transmission lines and continuing consolidation of systems are the outstanding features of the development of the electrical industry during the past year in the Middle West Division.

The erection of new big and economical steam-generating stations and the development of new water-power projects where they are practical have added to the power available. The building of new transmission lines into hitherto undeveloped territory has carried this power to nearly every quarter of this division, and the aggressive salesmanship of member organizations has opened up new fields for consumption.

Production has increased by 622,945,000 kw.-hr. during five years, being 3,019,752,000 in 1923 and 3,642,697,000 in 1927.

During the four years ended Jan. 1, 1928, nearly a quarter of a million new customers were added to the central stations. In 1924 there were 1,386,627 and in 1927 there were 1,617,200 customers. During the year 1927 there were added 77,500 new customers. The number of customers by classes and the increase were as follows:

| | 1926 | 1927 | Increase |
|---|---|---|---|
| Domestic lighting ......... | 1,249,800 | 1,313,300 | 63,500 |
| Commercial lighting ....... | 215,000 | 224,500 | 9,500 |
| Power and miscellaneous.... | 74,900 | 79,400 | 4,500 |
| Total .................... | 1,539,700 | 1,617,200 | 77,500 |

Thousands of miles of new transmission lines have been built and the voltages of many more raised. In Iowa alone 1,000 miles of new lines were constructed in each of the past two years. It is gratifying to have the electrical engineer of one of our commissions make the public statement that the character of the construction of the transmission lines in his state far exceeds the requirements of the commission. As a result of the extension of these lines service has been extended to all of the cities and most of the towns. In my state, Iowa, 99.7 per cent of the urban population is located in cities and towns that have electric service.

Don M. Sterns

The problem of the electrification of the farms of this great agricultural district is receiving the most assiduous attention of the engineers and operators. Many thousands of dollars have been spent in research work during this time to determine how energy can be used on the farm to the profit of the farmer and the industry.

Consolidations continue, giving the small communities the benefit of vast power pools, better service and lower rates. Speaking of Iowa particularly, and the same trend is equally noticeable elsewhere in the division, the number of separate and independent operating companies in 1922 was 149. On January 1, this year, the number was 27. During the same period 79 municipally owned establishments have been absorbed by the larger Iowa operating companies. Each of these towns is enjoying a lower rate, has better and more dependable service and all the reserve power necessary for the development of new industries.

Prospects for development during the present year are gratifying and there is every reason to believe that the increase in the use of energy will continue even more rapidly than during the past.

## Economic and Social Aspects of Rural Service

"I HAVE already said elsewhere to the power companies that having, in their own interest, extended their great power transmission lines through rural communities in order to connect one city with another, they have taken on an obligation to serve the rural population of the area in which they operate. This does not mean that they can run service to the last farm or perhaps even to the last village in that district, but it does mean that the power companies must view their obligation as having both an economic and social aspect.

"The power company cannot refuse country lines because they are unprofitable. They cannot ride the economic hobby to the point where electrical service is not generally available in the community. Nor, on the other hand, can they ride the social hobby, as some visionary persons urge, to the point of financial bankruptcy. Wise human judgment must be exercised in the service of the constituency of the power company.

"Rates, so far as possible, should be simplified. The slide rule is not as unerring as the engineer sometimes thinks. The power company cannot use it as the sole guide to the social needs of a community in which human understanding and human sympathies must be mingled with economics in order to get a practical result. The power companies should recognize this kind of obligation to the farmer, should study his needs, and within every reasonable economic limitation supply his service.

"The only economic limitation is that the power companies should be permitted to secure earnings from the community as a whole which will yield a fair return on the investment of the power company as a whole. Therefore, rates should, in my judgment, be made practical for the farmer, and the Public Service Commission should co-operate and even insist upon their establishment. Some part of the savings resulting from these great transmission systems should be applied to the extension of farmers' service rather than be granted wholly to the cities in the diminution of their rate. This is advantageous to the farmer and is sound for the city."

—OWEN D. YOUNG,
*Chairman of Board General Electric Company.*

the absorption of independent properties into the larger systems. The total length of transmission lines of 13,200 volts and over in these six states must approach close to 20,000 miles, of which probably not more than 15 per cent was in existence ten years ago.

Since Nebraska includes one of the leading utility exponents of vigorous sales activity, it is almost inevitable that the utilities of this region should be thoroughly imbued with the commercial spirit. That this spirit is at work in more than the merchandising of appliances is evident from the efforts of some of the companies to develop industrial load. In one year one company made industrial surveys in 23 of the larger cities on its system. These surveys included studies of labor conditions, available raw materials and other factors having a bearing on the locations of definite types of industries. This activity is not confined to the one company.

Virtually every utility in the north central area is merchandising electric appliances as a part of its normal function. In spite of the availability of gas service in all of the cities and many of the larger towns, electric ranges are being sold in increasing numbers. Refrigerators are selling in large volume against the competition of natural and artificial ice. Water heaters apparently are coming into appreciation from both utilities and customers.

In the field of rural service this region is a national leader. The first rural service project to receive country-wide notice was established by the Northern States Power Company at Red Wing, Minn. And down in southern Wisconsin lives G. C. Neff, who aroused the utility industry to a consciousness of its obligations and opportunities in serving rural districts. During 1927 his company added nearly 2,000 rural customers to its lines. All six of the states in this group are very active in rural electrification.

# *Southwest*
# Accumulates Momentum

Base-load stations are large factors in power supply. Transmission networks already widely established and are still growing rapidly. Commercial activity yields tangible results

By FRANK R. INNES
*Western Editor*

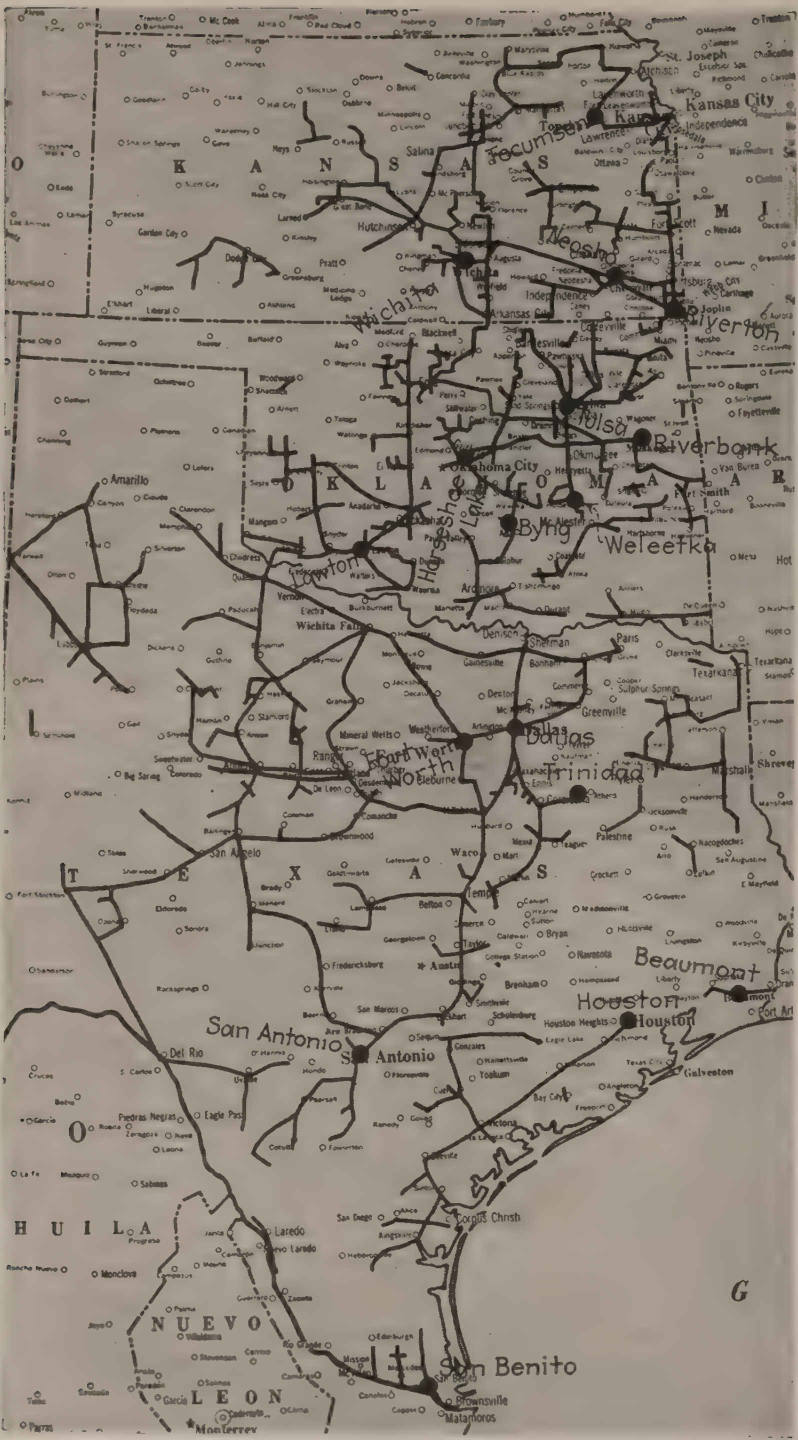
COMPARED with its status ten years ago, electric development in the Southwest has made more rapid progress than probably anywhere else in the United States. This development has been evident chiefly in extension of transmission lines, building of new generating stations or extension of old ones, spreading of service to new communities and consolidation of the smaller properties into larger ones for more economical unified service. The greatest improvements in economic and social conditions have apparently occurred chiefly in the sections where electrical development has been greatest. Regardless of whether general or electric development has forerun the other, either will stimulate the progress of the other.

Great as has been the progress of the last decade, the future is most enticing because this section has only started in its development. Many undeveloped mineral resources are waiting to be worked. The rapidity with which general development will occur will depend on the extent to which these territorial resources are made known to industrial capital, on attraction of industries to serve this great expanse which is now dependent on distant sources, continued extension of electric service and on co-ordinated participation of all business interests in making living conditions superior to adjacent sections.

The Southwestern states of Missouri, Kansas, Oklahoma, Texas, Louisiana, Mississippi and Arkansas are predominantly agricultural. The climatic range is great and the products of the soil include practically every fruit and vegetable known to the temperate zone. Cotton is common to most of these states and is easily the most important product of this territory. Industrial activity is more closely associated with the extraction of raw materials from the earth and with their preliminary processing than with the manufacture of finished commodities. Industry is growing more and more rapidly as new people come in. The population has increased 7½ per cent in six years—a gain of more than one and one-third millions.

As in other regions, electrical development here is not largely and directly affected by agriculture. However, the basic economic conditions determined by agriculture must be taken into account.

The production of wheat and corn in Missouri, Kansas, Oklahoma and in parts of the other states in this region amounts to about one-fourth of the total for the country. Cotton, rice, sugar cane, sorghum and a host of other



*Trinidad station burns lignite, Wichita and Dallas natural gas, Neosho uses stokers, and many plants are oil fired*

products make this territory of prime importance in the agricultural picture of the United States. Arkansas and Louisiana are leaders in pine lumber production, and the timber resources of the other states, such as Texas and Oklahoma, are considerable.

The mineral and allied resources of the region are tremendous. Oklahoma, Texas, Kansas and Arkansas are richly dowered with petroleum. Remarkably diversified mineral deposits also exist. Some are being worked, but most are not being developed at all. In the worked class are the zinc and lead deposits of Missouri and coal in some parts of Kansas and Oklahoma. Among the latent mineral riches of this country are the marble strata of Arkansas and the sulphur, graphite, quicksilver, diatomaceous earths, asphalt, lignite and the rare metals in Texas, Louisiana, Arkansas and Oklahoma.

During the past ten years the Southwest has been the scene of a widespread demonstration of the virtues and advantages of that politically criticised practice electric utility consolidation. Little evidence can be found that consolidated control and operation has been other than distinctly beneficial to the component utilities and the economic progress of the region in general. The great distances, the comparative smallness of communities, the frequent difficulties of obtaining adequate fuel and water for electric generation—all these and many other considerations make the Southwest an ideal territory for concentration of power generation at a few strategic points and for transmission to markets unfavorably situated for local or nearby generation.

One organization covers a major part of the states of Arkansas, Mississippi and Louisiana. Another spreads over as much of Texas as would comfortably contain four or five New England states.

The electric utility interests most largely represented in this region are the Electric Bond & Share Company, the Middle West Utilities Company, the Standard Gas & Electric Company, the Community Power & Light Company, the Cities Service Company, the North American Company and North American Light & Power Company.

State summations of generating capacities do not give a true conception of development in the Southwest, because scores of small plants are included, the total capacities of which amount to respectable figures. Many changes have involved the replacement of small plants by a few large generating stations, resulting in much higher system efficiencies. Some of these newer stations are: Tecumseh, Neosho and Wichita, in Kansas; Horseshoe Lake, Weleetka, Byng and Tulsa, in Oklahoma; Trinidad, San Angelo and San Benito, in Texas; Sterlington and Arsenal Hill, in Louisiana, and Remmel, in Arkansas.

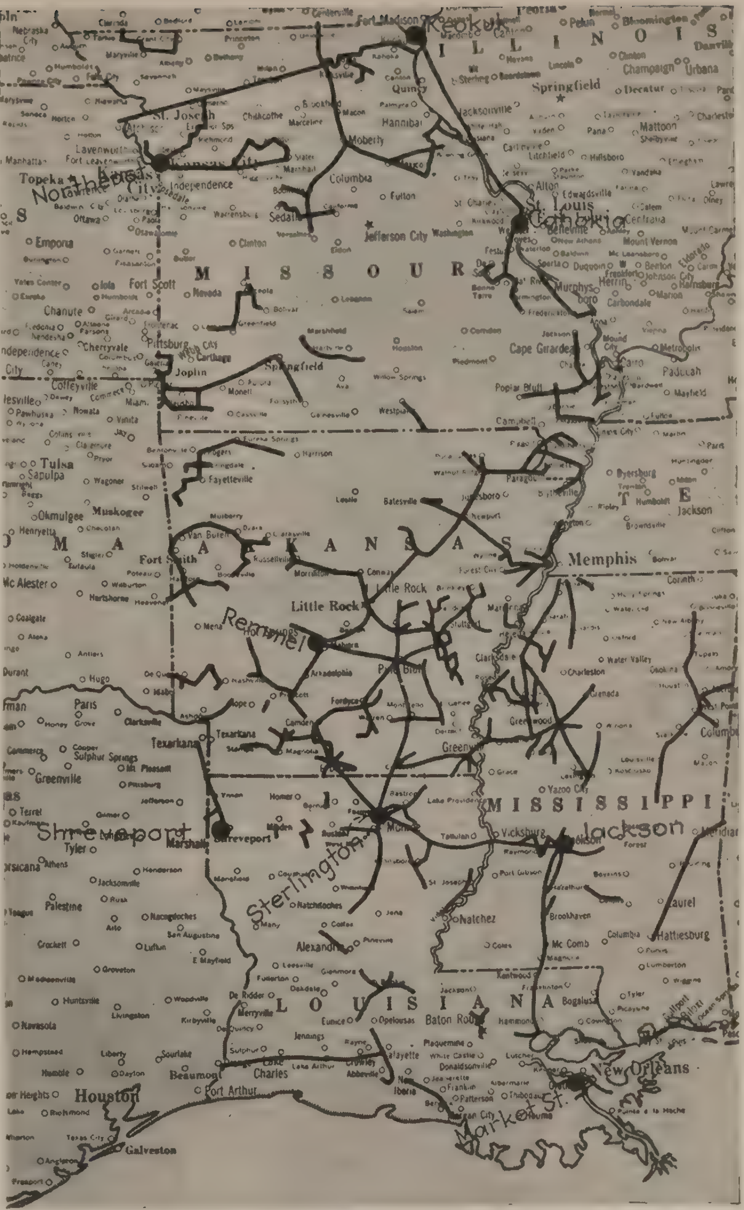
Considering new developments in steam plant design, the 10,000-kw., 1,500-lb. turbine at the Northeast station of the Kansas City Power & Light Company should not be overlooked. This machine will exhaust to the 350-lb. steam header. A project now under discussion by this company contemplates the installation of additional capacity in the recently absorbed 180-lb. street railway generating station, to operate at 700 lb. and exhaust into the 180-lb. header.

Among the stations in the Southwest, as elsewhere, there is wide divergence in fuels used and methods of firing. Pulverized coal systems, both unit and storage type, are to be found, as well as stoker installations. Neosho uses stokers on the new boilers; natural gas is burned at Wichita, Dallas, Sterlington; Trinidad uses powdered lignite, and a number of stations are oil fired. The performances of these stations over long periods average in the neighborhood of 18,000 B.t.u. per kilowatt-hour.

Most of the new stations are operated wholly on base load, the fluctuations being taken by the older and smaller plants remaining in the systems. Owing to the capacity effect of long transmission lines, power factor is easily maintained at close to unity. On one property the base-load station operates on Sundays and holidays at full kilovolt-ampere load and a leading power factor of 25 or below.

The amount of hydro power is not great in this region in comparison with the rest of the country. However, in the Ozark area in Missouri and Arkansas there are a number of promising hydro possibilities. Only one major project, at Remmel, Ark., has so far been developed. Above Remmel, on the Ouachita River, another project is under construction, and in the past few months the Insull interests have become associated with a projected development in Missouri. Texas also has a number of hydro power sites, some already developed and one on Devil River now under construction.

Of the present transmission network in this territory, probably not more than 10 or 15 per cent was in existence ten years ago. The increase of transmission mileage is due largely to the consolidation of independent properties, interconnection of contiguous systems, and development of natural resources, such as oil fields, mines, and quarries.



*Northeast station uses 1,000-lb. steam; Remmel is a hydro plant; Sterlington burns natural gas*

Although the systems in Missouri and Kansas are extensively tied together they are not so far flung as those in the five other states. Texas, for all its immensity, is practically covered by a continuous system of transmission lines. Oklahoma is crossed and recrossed with what amounts to a single transmission system, although quite a number of different companies are represented in ownership and operation. Extending north and south through Louisiana and Mississippi are the legs of a system that centers in Arkansas and nothern Louisiana.

A striking example of the value of interconnections between systems is furnished by the development of oil field load in Oklahoma. It also indicates a tangible value of holding company operation. At the beginning of the spectacular oil field rush of 1926-27 in Oklahoma it was not expected that the load would assume extraordinary proportions and no unusual provisions were made for it. But the success of the first few installations inspired more intensive and extensive selling effort and also caused a large number of oil operators to decide for themselves that they were going to have electric service if they could possibly get it. The result was that the peak demand on the utility system almost doubled inside of one year. Before the utility could increase its generating capacity it was imperative to supply energy from interconnected systems to the north, east and south. Meanwhile, the engineering and financial facilities of its parent company enabled the Oklahoma Gas & Electric Company to erect a new power plant and put it on the line in 85 days.

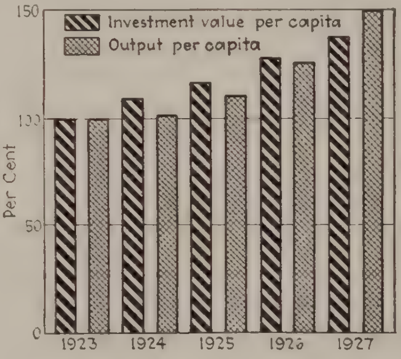
*No figures for 1921—these refer to 1923.

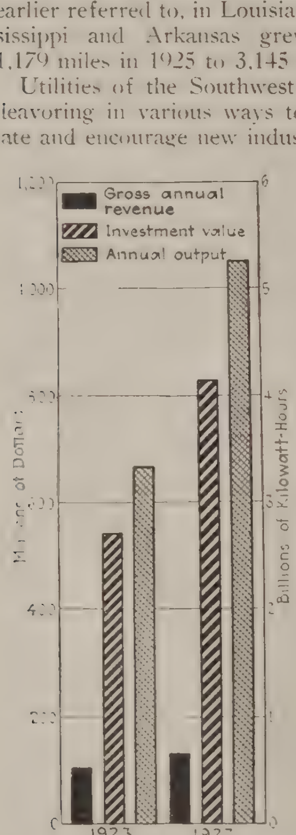
Between 1923 and 1927 the number of electric customers increased 14 per cent, to 97,168, but the connected load rose 100 per cent, to 254,476 kw., and the kilowatt-hour output skyrocketed 250 per cent, to 399,543,412, virtually 50 per cent more than the year before. The last two figures indicated the high load factor of the oil field load. To serve this load transmission lines had to be extended very rapidly. In 1923 there were 585 miles of line, whereas in 1927 there were 1,951 miles, 542 miles more than the year before.

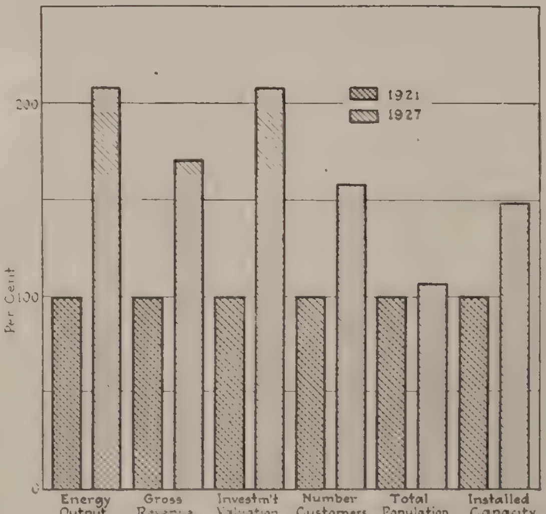
Other large systems of Oklahoma, Texas, Louisiana, Arkansas and Kansas can show similar records of growth. For example, one group of connected properties in Texas shows an increase of transmission mileage from 2,068 in 1925 to 5,296 in 1927. The system, earlier referred to, in Louisiana, Mississippi and Arkansas grew from 1,179 miles in 1925 to 3,145 in 1927.

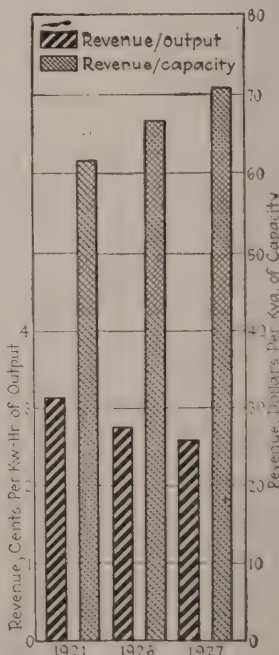
Utilities of the Southwest are endeavoring in various ways to stimulate and encourage new industries, to persuade new people to come into the region and to further their economic progress in every way. This work is done by all forms of publicity and sometimes by monetary help.

Practically all of the central stations in this territory have committed themselves to aggressive merchandising. Campaigns, house-to-house solicitation, special opportunities and other methods of getting the load on the lines flourish. Some companies have had rather disagreeable experiences with high-pressure selling, but the general opinion is that the fault was in the lack of control rather than in the method. In one Texas city domestic merchandise sales were pushed up to more than $40 per customer in 1927; a Kansas town reached $27. Sales of electric ranges are hampered in some localities by the cheapness of natural gas, which costs as low as 10 or 15 cents per thousand cubic feet of 1,100 B.t.u. gas. Refrigerators have had a wide sale on account of the long summer period and the difficulty, particularly in the small towns, of securing ice.









*Increased investment per capita and reduced revenue per unit of output show Southwestern contribution to public*

# *A Decade of Utility Progress*

*By Joseph F. Porter*
*President Kansas City Power & Light Company, Kansas City, Mo.*

*Joseph H. Porter*

ELECTRICITY has played a wonderful part in the development of our country in the past ten years. There has hardly been in that period an industrial achievement of any kind to which electricity has not contributed in an important degree. It is one of the very few commodities, to my knowledge it is the only one, that has steadily decreased in price to the user, while other costs for material and labor have as steadily increased. With the exception of the farming population, and the job of bringing electric service to this group is going along with rapidly growing momentum, there is hardly an individual in the United States who has not, or cannot have if he wants them, all the benefits, comforts and conveniences that electricity brings to its users. The use of electricity in homes has been extended far beyond the expectations of former years, although as yet that use has nowhere approached its limit. The average residence consumption not so long ago was about 180 kw.-hr. per year; today it is 425—an increase of 136 per cent. This indicates the great possibility latent in the residential load, and a signal accomplishment of the last ten years has been the comparatively recent appreciation of the tremendous potentialities of that load. It has been no small achievement of the industry to convince its members of the potential importance of the residential load and that electricity could be used in the home, profitably to both customer and utility, for more than a few lights. The greater achievement of complete development of domestic electric service still lies ahead of us—ten, twenty years, who can say?

I have spoken first of electricity in the home because that affects more people than any other application and because it is relatively a new thing with us and because while the sum of our efforts in this direction to date has seemed large to us, it is small in comparison with what there remains for us to do. In the applications of electricity to commercial uses there has been much progress, progress not only in the greatly increased consumption of energy for common and familiar uses, but also a remarkable widening of the field of application. While mechanical power remains the most important outlet for electric service in industry, there have been many new applications that were unknown or little considered ten years ago. Chief among these newer uses is industrial heating, a field of service that according to some men who speak with real authority will eventually make the power load seem small in comparison.

In support of the foregoing general remarks there can be instanced the progress of the city and company with which I am naturally most familiar. In 1918 the peak load of the Kansas City Power & Light Company was 26,400 kw.; in 1928 it is, so far in the year, 120,806 kw., an increase of 458 per cent. In 1918 the energy generated amounted to 118,192,608 kw.-hr.; in 1928 it will be nearly 500,000,000, an increase of more than 400 per cent. In 1918 unaccounted for losses were 18.52 per cent; in 1928 they are 11.26. Taking into consideration this 39 per cent reduction in losses, the amount of energy sold in 1928 will be about six times the amount sold in 1918.

The past ten years in Kansas City has seen many changes in the generation and distribution of electricity. These changes have been the milestones of definite economic progress in the community. Among them are listed the replacement by many incandescent lamps of the few sputtering arcs that were only a short time ago the best that could be used for street illumination; the installation of transformer substations in residence districts in place of noisy converting machinery; the changing of the power system from 25 to 60 cycles; the building of a large new generating station; automatically operated substations installed throughout on both alternating- and direct-current distribution systems, and a host of minor improvements. All of these changes have been made with the single view of producing a more reliable service at a lower cost to the consumer because it is good business to do so.

These figures and this information on the Kansas City utility are not given because this company has performed exceptionally well in the past ten years. Some companies have done better and, by the same token, some have done worse. But there is no intent at comparison here; it is only desired to show the general progress by a specific instance. Looking back over ten years, the record of the power and light industry has been one of constant progress, efficient operation and fair treatment of customers and stockholders. Any company or industry that lives by these policies has built on a secure foundation. Adherence to these policies assures our continued success in the future. The increasing use of electricity in the home, on the farm, in industry and by the railroads is evidence of the development yet to come. Electricity is the most efficient, economical and convenient source of power. So long as it holds this position and so long as the business of its supply is managed according to the policies here recited the future holds for us continued development and continued success.

# Letters from Our Readers

## *Matter and the Senses*

*To the Editor of the* Electrical World:

In regard to the interesting editorial entitled "What Is the Atom" in the April 28 issue of the Electrical World I should like to submit the following comment, in the hope that you may find it worthy to publish. Perhaps confusion exists in regard to the terms matter and energy, and in order to clarify these concepts it is necessary to consider human sense perception. Is it not well agreed that there are planets of varying size, then bodies, substances, molecules, atoms and electrons? Are there not electrons in atoms, atoms in molecules, molecules in substances, substances in bodies?

Why not go on and reasonably argue that the electron is probably divided into smaller units, magnetrons, for instance. Just as electricity is the expression of moving electrons, then magnetism is the expression of moving magnetrons! Light is then moving electricity (electrons) in matter. Daylight is moving electricity in the earth's atmosphere. Heat is then moving magnetism in matter, especially in solid matter!

What is matter on the above basis? Matter is locked-in energy perceived through the human senses directly or aided with instruments! The electron is matter since it was identified through the oil drop experiment of Dr. R. A. Millikan. Matter is real because it is perceived through the senses unaided, as in the case of bodies and substances. Matter is real because it can be perceived by the human senses through the use of instruments, as in the case of planets, molecules, atoms and electrons!

What is energy on the above basis? The higher manifestations of energy are unlocked matter not humanly perceived, yet to be controlled, relocked into matter and put to work for mankind. Lower manifestations of energy are partially unlocked known matter.

For instance, solar energy is unlocked, unknown sun matter. Heat energy from a wood fire is unlocked known matter—wood. In the first case, the control that unlocks the energy is unknown to us. In the second case, the control is in the hands of mankind and involves fire and the process of combustion (oxidation). No one knows when fire was first started, but some one obtained the idea, from some source, of rubbing two sticks together. In other words, Prometheus stole fire from the Gods!

Ordinary matter is locked-in energy whose rate of radiation is so slow, from the standpoint of human sense perception, that the radiation is unperceived. For instance, a sheet of glass is matter which is locked-in energy. The radiation rate of this locked-in energy is too slow to be humanly perceived.

Higher orders of matter, for instance radium, are locked-in energy whose radiation rate is perceived by the human senses. All matter radiates energy; in other words, it is slowly or rapidly unlocking! The unlocking of energy from matter—energy radiation—and relocking of energy into matter again are all relative actions involving time and human sense perception. The higher orders of energy unlock and relock the lower orders, thus deforming and reforming matter. The control of this action is slowly vouchsafed to mankind in measure as such control is merited! C. L. Kasson.

1165 Massachusetts Avenue,
Boston, Mass.

## *Dividends Paid on Profits, Not Volume*

*To the Editor of the* Electrical World:

The article "Profit vs. Volume in Pricing," by W. L. Churchill, that appeared in the March 24 issue of the Electrical World has proved of interest to us as it must to every company engaged in present-day competitive selling. Many of us have fallen into the habit of thinking that business is good or bad depending on whether it is ahead or behind last year's volume. Let two business men meet and the first question is, "How's business?" and the next is, "How does it compare to last year?" How many times have you heard one business man ask another, "How're profits?"

Trying to beat last year is the great American business game, and it's quite worth while if the players will only remember to keep their eye on the ball of "Profits." When business becomes a mad scramble, as I am afraid it has, after volume, let profits fall where they may, we are headed for trouble.

Purchasers wise in the lore of tendencies, sensing the fight for volume, dangle large orders before salesmen and the lure is a "better price." The better price is always a lower price and a lower price is very often a profitless one, but, rather than a lost order, a lost profit is accepted. And so business finds itself in what may prove to be a vicious circle. Very often the purchaser is blamed because he takes advantage of a buyer's market and drives a neat bargain, profitless though it may be. And yet the purchaser is out to buy at the lowest figure and can never be sure the figure he has before him is the lowest until he tries the salesmen to find out. And the salesman, driven for volume and his company striving for the same thing, cuts and cuts, until there's no profitable margin left.

The purchaser must realize that after all is said and done business to be mutually profitable must be done on a live and let live basis. He must have confidence in the companies he wants to do business with and, having that confidence, concede to those companies a fair profit on the merchandise he buys, just as he expects to make a fair profit on the merchandise he sells. This thought is admirably summed up in a recent advertisement of the Western Electric Company. Speaking of itself as a buyer of the Bell System, it says: "It (the Western Electric Company) must buy at prices which are fair to the Bell System. It must buy at prices which are fair to the seller, because he must be able to continue in business and prosper, to remain a reliable source of supply."

If every purchaser of electrical equipment in this country had a platform of that character, most of the ills spoken of by Mr. Churchill would disappear.

The seller, too, should have a platform. He should throw away his target of volume and drop his sights to profit. He should, as he does, charge a fair price for his goods and his service and take no business that returns no profit. That may be Utopia, or may be achieved in the millennium. I think it will be achieved when shrinking yearly profit balances will drive business to the realization that following blindly after volume is following the will-o'-the wisp that can lead only to disaster.

We in our company are trying to build a business on payment received for service rendered and merchandise delivered. We know that dividends are and can be paid only on profits, not volume. Albert L. Salt,

Graybar Electric Company, President.
New York City.

# Digest of Electrical Literature

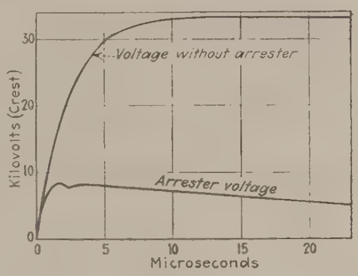
## *Generation, Control, Switching and Protection*

*Heat Losses in Direct-Current Armature Conductors.*—W. V. Lyon, E. Wayne and M. L. Henderson.—The authors have endeavored to indicate that it is incorrect to assume, while there are extra losses in the armature coil of a direct-current machine when it is undergoing commutation, that during the major portion of the time, since the current is steady, the loss in the coil is correctly computed by squaring the value of the current and multiplying by the true or ohmic resistance of the coil. The disturbance in the coil current produced by the process of commutation persists throughout the cycle, so that at no time is the current uniformly distributed over the cross-section of the conductor. Although the disturbance and resulting extra loss factors are greatest during commutation, the extra losses are present at all times, even while the current in the coil is steady. The procedure for determining extra losses is given and the case involving several coils side by side is likewise considered. It is also suggested that it is more important to laminate and properly arrange the armature conductors of a large direct-current generator than it is to do so in the case of an alternating-current machine.—*Serial No. 552 Publications from the Massachusetts Institute of Technology,* March, 1928.

*Protection of Supervisory Control Lines.*—Edward F. W. Beck.—Supervisory control lines used in the remote or automatic control of electric plants are subject to overvoltages dangerous to insulation and to operators. These overvoltages may be caused by lightning, crosses with the power lines or induction from them. Open wire control lines are influenced by all of these, cables with grounded sheaths are immune to disturbances caused by lightning or other electrostatic induction and are more or less safe from crosses. The ordinary cable is still subject to high voltages by electromagnetic induction when a fault occurs on the power line. These voltages may be dangerous not only to apparatus but also to the cable insulation. Protection by means of lightning arresters is therefore necessary. Calculations show that even if the apparatus locations are protected, high voltages may occur along the lines if the transmission line fault is between stations. This may cause a cable failure, so that it is advisable to protect the cable at certain intervals. Supervisory control protectors may be called upon to discharge heavy currents of appreciable duration. This requires extremely sturdy arresters and the conditions are met by a spark gap of a special design operating in argon at a reduced pressure. The author suggests that specially made cables will shield the line from extraneous disturbances and that in large installations such precautions may prove desirable.—*Journal of the American Institute of Electrical Engineers,* May, 1928.

## *Transmission, Substations and Distribution*

*Protection of Station Equipment on High-Voltage Transmission Lines.*—K. B. McEachron.—An interpretation of the effect of transient voltages on transmission lines and transformers has been undertaken by the author. Extensive consideration has been given to: Impulses due to overvoltages induced by lightning; insulator flashover characteristics and phenomena; the insulation of lines and transformers, and to lightning arresters both as regards the line and location for best results. The author concludes that in designing a high-tension system careful consideration must be given to all of the factors affecting the protection of the system against lightning. The effect of high towers, long spans, high line insulation, transformer and bushing strength and a proper relation and balance of the values involved must be considered so that no part of the system will be unduly stressed.—*General Electric Review,* May, 1928.



*Effect of lightning arresters on voltage-time characteristics*

## *Hydro-Electric Development and Steam Equipment*

*Characteristics of Modern Stokers.*—F. H. Daniels.—The characteristics demanded of modern stokers and the manner in which these requirements are met by the travelling grate and multiple-retort underfeed types has been outlined in a discussion of the several methods of securing the desired results. A consideration is offered of the plans for securing air control along the length of the retort and of duplex firing of multiple-retort underfeed stokers. The advantages of utilizing water tube furnace walls has been considered and the economic considerations involved in their application to generating station use have been reviewed. In connection with the duplex firing scheme involving the use of pulverized fuel and stoker feed in the same combustion chamber it is stated that the only increase in cost would be the price of the unit pulverizer and burner and that this would easily justify itself by reason of the increased capacity obtained from the boiler during peak hours. The tendency of the stoker to show a large drop in efficiency at high capacity would be largely offset and it would not be necessary to sacrifice economy to get capacity.—*Transactions of the American Society of Mechanical Engineers,* January-April, 1928.

*The High Cost of Fuel Saving.*—W. Trinks.—A comparison of the progress in engineering with the tendency toward fuel saving is offered by the author. Some of the reasons for hesitating to adopt new equipment that will save a large percentage of fuel wasted by the older methods are pointed out. It is indicated that in most cases it is less expensive in the long run to retain the old equipment than to install the latest types with their economies. Mention is made of analogous practices in other fields.—*Transactions American Society of Mechanical Engineers,* January-April, 1928.

## *Units, Measurements and Instruments*

*The Flow of Viscous Liquids Through Pipes.*—A series of charts for use in examining the various factors involved in the flow of viscous liquids through pipes is presented in this discussion. One permits the determination as to whether the flow will be viscous or turbulent, another develops a stream-line consideration, and the other two, which are particularly applicable to turbulent conditions, may be applied to graphical determination of the several terms in the equation developed by Prof. C. H. Leeds for such work.—*Engineering (England),* April 27, 1928.

*Demand Metering Equipment.*—Stanley Stokes and Leslie V. Nelson.—The authors have considered the special applications involved in the development of demand metering equipment. Public utilities supplying electric power are continually finding themselves confronted by problems a little different from anything in the past. New interconnections with superpower plants, and transmission lines often present involved metering installations. The one herein described has to do generally with such a condition and specifically has to provide for metering the simultaneous composite demand of an ultimate installation of 48 separate feeder circuits. It is believed that this is the largest installation of its kind so far attempted. The importance of this particular job required a very exacting study of all of the factors and the operating results to date appear to be entirely satisfactory. A novel scheme has been incorporated in the daily routine of handling the demand meter tapes. A general description of this is given and a few details of the physical installation are cited, which show the extreme care used throughout the whole installation. While this application is specifically designed for metering, the principles involved are applicable to numerous other uses, some of which are mentioned.—*Journal of the American Institute of Electrical Engineers*, April, 1928.

### *Motors and Control*

*Power Requirements in Cotton Mills.*—H. H. Bodge.—The power requirements in the various phases of cotton mill activity are reviewed in connection with process characteristics. A tabulation of the power requirements for the many types of machines required for this work has been included.—*Electrical News (Canada)*, May 1, 1928.

### *Heat Applications and Material Handling*

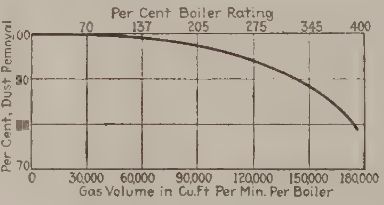
*Industrial Electric Heating Installations.*—The Industrial Heating Committee of the N.E.L.A. has issued a serial report superseding previous publications issued by the same division. The heating operation, product, plant, heating equipment, size, insulation, operating temperature, heating cycle, load in pounds, pounds per kilowatt-hour, the form of heating replaced by the electric application, the responsibility for the installation and the manufacturing results, user and central station factors, and several others, are considered for a number of installations dealing with the melting of metal, hardening and carburizing, annealing and normalizing, tempering, handling of vitreous enamel, baking of enamel and Japan and the baking of cores, and miscellaneous installations.—*Report National Electric Light Association*, April, 1928.

*Arc-Welded Steel-Frame Factory Building.*—Frank P. McKibben.—In connection with a description of the construction methods used in erecting an electrically welded steel-frame factory building, the author has suggested that this process is to be recommended for general use in the welding of bridges and buildings, but that application should be confined to responsible designers, fabricators and engineers who may apply it only where it has well-defined advantages over any other known method of building and who will exclude it where not suitable. Several problems arising in connection with such work are mentioned, including the necessity for securing building codes which will permit the use of welded construction, the need for a simple, practical series of accomplishment tests for use in employing welders on important work, more extensive use of jigs in fabricating shops to reduce cost of assembling, automatic welding machines depositing continuous or intermittent fillets which should be further developed to reduce construction cost and detail standardization which should be effected to facilitate the adoption of structural welding practices to general use.—*General Electric Review*, May, 1928.

### *Electrophysics, Electrochemistry and Batteries*

*Electroplating on Aluminum and Its Alloys.*—Harold K. Work.—It is stated by the author that electroplates of most metals on smooth aluminum surfaces are of doubtful value unless heat treated. Plating on a roughened surface is recommended as being a practicable procedure. Methods of plating the common alloys are given. A dip is described for commercially pure aluminum which roughens the aluminum and simultaneously forms an immersion layer on the surface. For alloys containing an eutectic network, a dip which attacks one constituent of the network is advised. Where strong alloys are plated an excellent product is easily obtained, providing the alloy has been subjected to the usual heat treatment to develop its strength.—*Report of American Electrochemical Society*, April, 1928.

*Electrical Precipitation.*—A. Grounds and H. W. C. Henderson.—A general outline of the several methods of securing electrical precipitation of solid material in gaseous suspension is considered by the authors. Practical applications to industrial problems and to the elimination of the dust from stack gases are given. The efficiencies and the practices adapted at the generating station of a large utility are outlined in connection with this discussion.—*Electrical Review (England)*, April 20, 1928.



*Efficiency of dust removal at pulverized fuel plant*

### *Telegraphy, Telephony, Radio and Signals*

*Propagation Characteristics of Sound Tubes and Acoustic Filters.*—W. P. Mason.—The process of measuring the propagation characteristics of uniform sound tubes and acoustic filters is complicated, according to the author, by the reflections which may occur at the ends of these structures. The present discussion applies some theoretical considerations in connection with the effect of these reflections. In making the measurements, the testing device involved is inserted in an acoustic transmission system, and the resulting changes in the magnitude and phase of the transmitted wave are measured. The actual observations are made in electrical circuits connected with the terminals of the acoustic system by loud speakers. The impedance of the acoustic system at the point of insertion is made an acoustic resistance. For measurement on straight tubes, these resistances as used are of such value as to prevent any appreciable reflections from the ends of the tubes. The results of the measurements indicate that the Helmholtz-Kirchoff law is invalid, while the results of measurements on acoustic filters are in good agreement with the theoretical results previously obtained.—*Reprint B-295, Bell Telephone Laboratories, Inc.*

*Electrical Measurement of Communication Apparatus.*—W. J. Shackelton and J. G. Ferguson.—A description of precision high-frequency measurements of a fundamental type, with special emphasis on measuring circuits rather than on the types of apparatus measured. Standards of frequency, resistance, capacitance and inductance are briefly discussed. Bridge measurements are described for the measurement of frequency, inductance, effective resistance, capacitance, dielectric loss, capacitance balance and inductance balance. Circuits for the measurement of other high-frequency characteristics such as attenuation, gain and cross-talk are included.—*Reprint B-294 Bell Telephone Laboratories, Inc.*

### *Miscellaneous*

*A Metallographic Study of the Path of Fatigue Failure in Copper.*—Herbert F. Moore and Frank C. Howard.—The study of the failure of metals under repeated stress, commonly known as fatigue, has usually been carried on by means of mechanical tests of strength. The present investigation involves the metallographic examination of the nature and mechanism of the progressive fracture which apparently constitutes fatigue failure. As a result of this investigation the authors conclude that etching with concentrated nitric acid brings out the intra-granular structure consisting of laminas separated by planes especially sensitive to chemical attack; specimens of rolled copper, subjected to repeated flexure until a fatigue crack develops, show a surface disturbance of the metal in the vicinity of the crack; the surface disturbance is visible in micrographs of unetched specimens by lines; the rolled copper tested had in it so few inclusions that any tendency of the crack to take a course from inclusion to inclusion was not in evidence, and that specimens of rolled copper etched after the development of a fatigue crack showed no evidence of any change in crystalline structure and that after the surface had been eaten away by the etching reagent the disturbed region in the vicinity of the crack was much less in evidence than on the unetched surface.—*University of Illinois Bulletin*, May 15, 1928.

# News of the Industry

## N.E.L.A. Program in Final Form

*O. W. Knauth, Department-Store Merchant, and C. E. Paige, Gas-Company Official, Added to Those Who Will Address the General Sessions*

COMPLETING the program of the National Electric Light Association as printed in the ELECTRICAL WORLD last week (page 1031), there will be two addresses not previously included—one on "Fundamentals of Electrical Merchandising," by Oswald W. Knauth, vice-president R. H. Macy & Company, New York, to be given at the second general session, on Wednesday morning, June 6, and the other on "Accident Prevention," by C. E. Paige, vice-president Brooklyn Union Gas Company, to be given at the third general session, on Wednesday afternoon. The address on "Government and Business," by John E. Edgerton, president National Association of Manufacturers, has been transferred to the third general session. It was previously scheduled for the first session.

The following titles have been selected for general-session addresses previously not designated otherwise than by the name of the speaker or by a general title since made more specific: Tuesday morning, "Radio's Relation to Electric Light and Power," H. P. Davis, chairman of board, National Broadcasting Company; Thursday morning, "The Decentralization of Industry," Governor Dan Moody of Texas; Thursday afternoon, "Labor's Part in Electrical Development," Hugh Frayne, American Federation of Labor; Friday morning, "The Power Industry in the Marketplace," James H. McGraw, president McGraw-Hill Publishing Company.

## Senator Wagner Introduces Anti-Federal Court Bill

Another bill has been added to those pending in Congress designed to restrict the jurisdiction of federal courts in cases affecting the rates charged by public utility companies. Senator Wagner of New York is the father of the new measure, which sprang from the decision of a United States statutory court allowing the Interborough Rapid Transit Company of New York City to increase its fare. The postponement last Monday until October by the United States Supreme Court of argument on the appeal from this decision will probably operate to prevent any vigorous agitation over the proposed legislation at this session of Congress.

Senator Wagner argued that the local utilities are created by the state and receive permission to do business and get their special franchise and monopoly privileges from the state or municipalities. He declared that the source and right of all the utility powers is in the state. "But," he added, "when their duties are in question the utilities are showing a marked preference for the federal courts and an antipathy to the jurisdiction of the state courts. Through their ability to raise the constitutional question local public utilities have been able to exercise choice and thereby to secure an advantage over the municipalities and residents of the communities wherein they do their business. There is to my mind no sound reason why a local public utility should have the advantage of a choice between two systems of law and two sets of judges."

## Conferees Agree on Muscle Shoals

### Their Bill Goes a Step Farther than the House Measure to Put Government Into Business—School Issue Looms Large in Trade Commission Inquiry

BY PAUL WOOTON
Washington Correspondent of the ELECTRICAL WORLD

SUCCESSFUL negotiation over the Muscle Shoals bills in conference between the two houses is announced by Senator Norris, father of the original Senate measure. After the House of Representatives had narrowed the scope of the business activities into which the government is launched by the proposed legislation, the conferees rewrote the bill in a form more objectionable to industry than the measure reported by the House committee. Under the conference bill the "Muscle Shoals Corporation of the United States" is directed "to operate existing plants" and to construct, maintain and operate experimental or producing plants at or near Muscle Shoals for the manufacture, distribution and sale of fertilizer or any of the by-products of the same.

As this is written, the general expectation on Capitol Hill is that the President will veto a measure which some of its opponents go as far as to term a "naked and unashamed attempt to establish communism in the United States as a national policy." The large vote for the measure in each house is explained on the ground that Congress is anxious to get rid of Muscle Shoals and on the ground that many votes were obtained through "trades" on flood control, farm relief, Boulder Dam and other measures.

Just as the legislation provides for the setting up of the government in the fertilizer and chemical businesses, it also thrusts Uncle Sam into the power business and introduces the Federal Power Commission as a regulating body in the several states where Muscle Shoals power will be sold. The new federal agency is directed to sell power to states, counties, municipalities, corporations, partnerships or individuals, and must give preference to "states, counties or municipalities purchasing said current for distribution to citizens and customers." The bill provides that power is to be distributed equitably among the states within transmission distance of Muscle Shoals. This insures its dissemination into a number of states. Wherever any Muscle Shoals power, regardless of how small the quantity may be, is intermingled with other power the Federal Power Commission is to determine a reasonable, just and fair price which the ultimate consumer is to pay.

The measure also authorizes the construction of the Cove Creek dam across Clinch River and the installation of equipment sufficient to generate 200,000 hp.

#### UTILITIES AND THE SCHOOLS

Testimony taken thus far before the Federal Trade Commission reveals that representatives of the public utilities have been extremely assiduous in getting views held by the industry before students in schools and colleges. Some take the view that certain of the methods employed in this connection were questionable. It was apparent, too, as concerns utility representatives' efforts in general to promote the cause of private ownership with the public and with legislators, that a particularly bad impression was made in the instance where no record of payments had been kept and in another instance where the records had been destroyed.

On behalf of the utilities it is explained that pamphlets furnished educational institutions are not textbooks in the usual conception of the term. Since an industry subject to public regulation is peculiarly dependent upon an intelligent understanding of its affairs by the public, it was felt that every effort should be made so that the rising generation would have a grasp of the complexities of this highly technical industry. In this connection it is contended that this constitutes a thoroughly ethical type of public relations, as is evidenced by the use of those methods by trade associations, banks, insurance companies and other commercial activities.

Attention is called to the fact that a few years ago the electrical industry necessarily was entering upon new forms of corporate, financial and industrial organization. It was new to the people, just as the chain-store problem, for instance, is today. It was necessary to acquaint the public with these departures before there could be hope of their favorable reception. Moreover, it was found that instructors in schools and in the academic classes generally were inclined to be ultra-conservative and disinclined to approve the methods that went along with the necessity of trebling the per capita production.

The testimony before the commission has been perfunctory, for the most part. Well-known facts and conditions have been reviewed so that they may be formally before the commission in the record. One of the outstanding developments of last week was the testimony of Representative Douglas of Arizona, who attempted to put into the record material indicating the extent of the activities of the Los Angeles Bureau of Power and Light in an effort to put forward the municipal point of view. The material was ruled out, but it is believed that before the case is closed there will be a comparison of the methods employed by the utilities and by the advocates of public ownership. As the commission is required to recommend remedial legislation, it is thought that the other side of the picture must be shown to enable it to judge the general situation.

## Trade Commission Investigation Resumes Monday

Nothing of a new or startling nature was developed at the utility hearing of the Federal Trade Commission last Thursday, May 17, when S. E. Boney of the North and South Carolina Public Utilities Information Bureau gave testimony on lines now familiar concerning the publicity and educational efforts of that body. When the inquiry resumes next week, after a ten-day recess, officials from the New York State, Minnesota and Colorado bureaus will be examined as well as C. H. B. Chaplin, secretary of the Empire State Gas and Electric Association, whose evidence is scheduled for Monday.

## Chicago Home Rule Bills Are Rejected, 49 to 17

The traction bills, to consider which the Governor of Illinois called a special session of the General Assembly, as reported last week, and which would have given Chicago home rule over its public utilities, were killed in the Lower House on Tuesday. A motion to postpone consideration was carried by 49 to 17. Declaring that there is no hope of giving Chicago public utilities home rule at this time, Representative Michael Igoe of that city denounced Governor Small and Mayor Thompson as those responsible for the failure.

## Felix Deutsch Dead

*Head of A.E.G. Expires Unexpectedly in Berlin Two Days After Celebrating His Seventieth Birthday—Forty-five Years in Electrical Manufacturing*

CABLE dispatches from Berlin received on Saturday, May 19, told of the sudden death from heart trouble on the day before of Dr. Felix Deutsch, head of the Allgemeine Elektricitäts-Gesellschaft, whose seventieth birthday anniversary on May 16 had brought forth congratulations from President von Hindenburg and Chancellor Marx of the German Republic and from prominent industrial leaders in Germany and other countries. At that time Dr. Deutsch was reported to be in excellent health. Only last October he visited the United States for the first time, and an interview with him on the progress of the German electrical industry was printed in the ELECTRICAL WORLD (Oct. 15, page 801).

*Felix Deutsch*

With Emil Rathenau, Felix Deutsch was one of the founders of the German Edison Company forty-five years ago, and his life career was bound up with the growth of the German electrical industry from the smallest of beginnings to its present magnitude. For years he himself traveled almost continuously in developing markets for the A.E.G., the great manufacturing company which grew out of the German Edison Company. He succeeded Rathenau as head of this company. To him was due in large measure its successful weathering of war and post-war conditions, and last fall Dr. Deutsch was able to report that the company had in hand orders for steam turbines with an aggregate rating of 1,000,000 kw.

Dr. Deutsch was a Privy Counselor of Defense for Germany. He won distinction outside of business circles through his love for music and other arts, to which he contributed time and money. His judgment was sought by his government in international affairs. He urged renewing relations with the United States immediately after the war and was a prominent adviser in Germany's trade relations with Russia. He was a member of more than forty executive committees of commercial enterprises.

## Congress Votes Gold Medal for Thomas A. Edison

A joint resolution authorizing the Secretary of the Treasury to strike off a gold medal in commemoration of the achievements of Thomas A. Edison was adopted by the House of Representatives last Monday. Duplicate medals in bronze are to be made and sold at a price sufficient to cover the cost.

In reporting the resolution, which was introduced by Representative Perkins of New Jersey, the House committee on coinage, weights and measures estimated the monetary value of industries entirely based on the inventions of Edison or materially stimulated by his inventions at $15,599,000,000, distributed as follows: Motion pictures, $1,250,000,000; telephones, $1,000,000,000; electric railways, $6,500,000,000; electric lighting, $5,000,000,000; electric supplies, $857,000,000; fixtures, $37,000,000; phonographs, $105,000,000; car shops, $109,000,000; dynamos and motors, $100,000,000; batteries, $5,000,000; concrete, $271,000,000; telegraph, $350,000,000; wireless telegraph, $15,000,000.

## Toronto Hydro Commission Defends New Rates

In a report submitted to Mayor McBride of Toronto in reply to queries from him regarding the increase and adjustments in the rates for electrical energy of the Toronto Hydro Commission, that body says among other things:

"The idea that the new rates penalize the small householder at the expense *(sic)* of the larger householder is erroneous. Under the new rates 65,500 consumers in six-room houses and under will pay on the average 22 cents per month more for their consumption; 17,500 consumers in seven-room houses will average 32 cents more per month; 17,200 consumers in eight-room and nine-room houses will average 37 cents more per month, and 5,500 consumers in ten-room houses and over will average from 52 cents to $1.28 more per month. In no case where a small consumer takes 30 kw.-hr. per month or less can he pay more under the new scale than under the old."

## Arkansas Utilities Association Elects Officers

The Hot Springs convention of the Arkansas Utilities Association, held last week and noted on page 1029 of the ELECTRICAL WORLD, came to a close on May 16, when the following officers were elected: President, W. E. Bann, general manager Western Gas & Elec-

tric Company, Texarkana; first vice-president, R. E. Ritchie, Pine Bluff; second vice-president, G. W. Skow, Huntington; secretary-treasurer (re-elected) Rex I. Brown.

Two speakers from outside the utility ranks were Joseph Leopold, manager Southern Central Division of the United States Chamber of Commerce, who charged the average business man with failure to do enough thinking on questions of vital national importance, and D. Hodson Lewis, manager of the Little Rock Chamber of Commerce, who urged the need of a research bureau to aid in the industrial development of the state. Harvey C. Couch, president Arkansas Power & Light Company, was the chief speaker at the banquet. He dwelt upon flood control, in which he is taking a prominent part.

## A.E.C. Board Acts on Boulder Dam and Other Matters

At a recent meeting in Milwaukee, the administrative board of the American Engineering Council indorsed the creation of a commission of engineers as proposed in the Douglas bill to investigate the physical problems connected with flood control and development of the Colorado River. The program contemplated by the Douglas bill was approved "subject to the report of the aforesaid commission," present expenditures on the Colorado River to be confined to flood protection.

Arthur W. Berresford, president of the council, reported to the board the council's activity in the Mississippi flood legislation and presented the report of the committee on Boulder Dam, headed by Francis Lee Stuart of New York, which unanimously decided against the engineering feasibility of the proposal outlined in the Swing-Johnson bill. President Berresford also told of the progress of the movement to transfer to the Department of the Interior the public works functions of the government. The council has been energetically sup-as the Wyant bill. Government officials and departments, especially the Engineer Corps of the army, are, however, strongly opposed to the bill, and it has little chance this session.

A proposed amendment to a joint resolution passed by Congress in 1919, "for the purpose of promoting efficiency, for the utilization of the resources and industries of the United States," was opposed. "This resolution," Executive Secretary L. W. Wallace explained, "has to do with the so-called Garabed free energy generator. This question has been before Congress in every session in some form or other during and since the war. The American Institute of Electrical Engineers from time to time has urged the council vigorously to oppose this. The council's committee on patents has likewise acted. The intent of this legislation, as expressed in bills in previous sessions of Congress, has been opposed by the council. In the light of such authorization, the executive secretary wrote to a number of the members of the House of Representatives pointing out the fallacy of granting such a privilege and seeking their active opposition. The resolution has been favorably reported by the patent committee of the House and is now on the House calendar."

## Revised Report on Muscle Shoals Measure

*Bill Recommitted by Senate to Conferees, Who Make Important Change in Provision Regarding Manufacture of Fertilizer—Power Clauses Unchanged*

DISPATCHES from the Washington correspondent of the ELECTRICAL WORLD received as it closes its forms and supplementing his letter on page 1113 (already on the press) say that after it had been found that the Senate would not approve the original conference report on the Muscle Shoals bill, which provided for the manufacture of complete fertilizer on a commercial scale, the confereees were instructed to bring in another report limiting operations to manufacture on an experimental scale. The authority to distribute and sell fertilizer, or any of the byproducts of its manufacture, was eliminated. The provision for the construction and operation of new plants and facilities was stricken out, and the policy of the government in the utilization of the Muscle Shoals properties was declared to be for the fixation of nitrogen for agricultural purposes. No change was made in the power provisions of the bill, and the construction of the Cove Creek reservoir is provided for in the second conference report, as in the first.

It was estimated that the conference bill first presented to the Senate could muster only twenty votes. In addition to the fertilizer and Cove Creek provisions, it is thought that many Senators had come to realize that it would be difficult to dispose of the surplus power to advantage under the terms of the resolution. Any lease of power would have to contain a clause providing for its recall, should it be needed for fertilizer production. Under the conditions set up by the bill it was evident that the surplus power would have to be sold at dump prices. There also was objection to the preference accorded municipalities. The bringing in of the Federal Power Commission as a regulatory authority also aroused opposition on the ground that it would infringe upon the regulatory activities of the several states. Despite all of these objections, however, the conferees, as just stated, made no changes in the power provisions of the bill, which now awaits a final vote.

# Debate Rages on Boulder Dam Bill

### Arizona's Congressmen Fight Valiantly Against Its Passage—Douglas Dwells Upon Engineering Difficulties and Economic Phases—Receives Ovation in House

DEBATE on the Swing-Johnson Boulder Dam bill raged in both the House of Representatives and the Senate on Tuesday, May 22. In the House chief attention was attracted to Congressman Leatherwood of Utah, who made a sensational speech, vigorously attacking the bill, the Los Angeles municipal government and William R. Hearst. The latter he accused of using his newspapers to misrepresent the Boulder Canyon project and in an attempt to benefit the Los Angeles Bureau of Power and Light, with which the Congressman said Mr. Hearst is allied, at the expense of the federal taxpayer. He called the Swing-Johnson proposal "an attempt at a deliberate steal for the benefit of a political group in southern California, for the benefit of the real estate speculator in California and for the benefit of newspapers owned by William Randolph Hearst."

In the Senate, after Senator Johnson, sponsor for the bill in that chamber, had paid his respects to Senator Smoot, a leading opponent, and charged him with obtaining some of his material from "the great power interests," Senator Hayden of Arizona made an extended speech, again advancing his three objections to the legislation. The bill, in his opinion, is an attempt to coerce sovereign states, provides for an unjust division of the waters in the lower basin and fails to compensate Arizona and Nevada for the use of their resources for the benefit of California.

Opponents of the bill were further cheered in the House on the following day when an ovation marked the conclusion of a speech by Representative Douglas of Arizona against the bill. Mr. Douglas made the point that insurmountable physical difficulties exist at the proposed site and urged that further engineering studies be made before public funds are wasted in an effort to accomplish an impossible task. He explained that the excavation would require a movement of material comparable with that handled in the operations of the Utah Copper Company. To accomplish that task under the limitations of the terrain and the short working season, he declared, would require a superhuman effort. Mr. Douglas also dealt at length with the economic phases of the problem and made the point that Secretary Hoover never had passed upon the cost estimates or the details of the project.

Effective speeches in favor of the bill were made by Representative Burton of Ohio, who argued that an improvement of such vast importance should not be delayed because of the failure of one state to join with the others in the basin, and by Representative Crail of Los Angeles, who declared that the coastal cities of southern California will enter into contracts with the government to purchase all of the power that can be developed at Boulder Dam and that every dollar would be returned to the Treasury. He took issue with the contention that Boulder Dam power would not be able to compete with that generated by steam, pointing out that the nearest coal fields are 800 miles from Los Angeles and maintaining that petroleum cannot be depended upon as a permanent source of boiler fuel.

## Hoosiers Discuss Vital Power Problems

*Joint Convention at Indianapolis Takes Up Questions of Policy—Opposition to Government Encroachment—Public Relations and Rural Service*

INDIANAPOLIS was the meeting place on Tuesday, Wednesday and Thursday of this week of the annual joint convention of the Indiana Public Utilities Association, the Indiana Electric Light Association and the Indiana Gas Association. These bodies united in a dinner on Wednesday evening, at which the chief address was made by William H. Onken, Jr., editor of the ELECTRICAL WORLD, who took as his themes the inability of the government to perform economic functions with any measure of profit or service to citizens, the national development and prosperity that have followed upon the enabling legislation of a generation ago as distinct from the hampering and crippling of business that he saw threatened by actual and impending disabling legislation of the present day, and the apparent incapacity of many people to discern the difference between political ambition and disinterested service. These points and others which he held to be vital and important to the country as a whole, as well as to the electric light and power industry, now under investigational fire, were effectively set forth by the speaker.

The meetings of the Electric Association got under way with an address by its president, R. M. Feustel of Fort Wayne, who asserted that the present occupation of this and similar bodies must be with matters of policy. This idea was amplified by T. F. English, president of the Great Lakes Division, N.E.L.A., who stressed the point that the electric utility business rests on a mutual interest of the public and the utilities, the one to be served fairly and economically and the other to enjoy freedom to work out its problems.

An opinion that farm service can be profitably undertaken on the basis of $120 per year from each customer was expressed confidently by G. C. Neff, who instanced the experiences of his own company in urging upon those present the necessity both social and economic for the development of this class of business. In the same strain C. V. Sorenson told of rural electrification progress and plans in Indiana. Specific instances of electrical applications to farm uses were discussed by T. E. Heinton of Purdue University.

A paper entitled in the program "A Few Comments on Commercial Activities," by W. H. Sammis, resolved itself into a comprehensive presentation of the aims and accomplishments of the Great Lakes Commercial Section. The session closed with a short but pertinent address by Harry Wenger, chief engineer of the Indiana Public Service Commission.

The second day of the convention, which was given over to the activities of the Indiana Public Utilities Association, was one of continuing interest. After the address of President A. W. Brady, advances in the art of accident prevention were described by W. R. Hirst. Harvey Harmon, a member of the Indiana Public Service Commission, then spoke on the subject of regulation. His remarks were pointed by the citation of manners and ways in which utility companies could improve their relations with the public.

Miss Theresa F. Carroll, chairman of the women's committee of the Great Lakes Division, outlined the work of this committee. Quoting President Coolidge's now historic remark concerning government in business, John B. Malling made a well-reasoned argument against public ownership based on the intention of the framers of the Constitution of the United States to fit that instrument to the changing conditions of future generations. Finally, Morse Dell Plain emphasized the need for proper training of those engaged in company management and supervisory functions. As management expects from workers a proper fulfillment of their duties, so the workers have a right to expect from management understanding supervision and control, he said.

New officers elected for the ensuing year by the Indiana Electric Light Association were: President, Norman A. Perry, president Indianapolis Power & Light Company; vice-president, C. V. Sorenson.

## Great Lakes Engineers Meet in Chicago

With a total attendance of 160 at the committee meetings, the Engineering Section, Great Lakes Division, N.E.L.A., met in Chicago on May 10-12. The committees that appeared to hold most interest, judging from the numbers trying to crowd into the rooms, were the electrical apparatus, underground, overhead lines and meter, although the inductive co-ordination, hydraulic power and accident prevention meetings were well attended also. The apparatus committee received two excellent reports on the current-carrying capacity of copper busbars and bus stresses under short-circuit conditions. These reports were compiled from tests made by the Commonwealth Power Corporation. A detailed report on the operation of high-voltage transmission lines, including tabulations of outages and their causes on 57 lines of above 100 kv., was presented to the overhead systems committee. The next revision of the National Electrical Safety Code was discussed in this committee, and action was taken to arouse interest in this subject among member companies so that present onerous requirements of the code may be corrected. At the general meeting, which was presided over by F. E. Andrews, chairman of the section, W. L. Abbott, chief operating engineer of the Commonwealth Edison Company, made an address on "After the Coal is Gone—What Then?"

## Maryland Fight Ends

*Consolidated Gas, Electric Light & Power Company Buys Northern Maryland Power from Philadelphia Electric, Subject to Commission Approval—Price Said to Be $500,000*

CONTROL of the Northern Maryland Power Company, operating in Havre de Grace and neighboring territory, has, assuming the consent of the Maryland Public Service Commission, passed at last to the Consolidated Gas, Electric Light & Power Company of Baltimore, whose contest with the Philadelphia Electric Company over this property has for more than a year been keen. (See ELECTRICAL WORLD for April 14, page 779.) H. A. Wagner, president of the Baltimore company, issued a statement on May 16 saying:

"The directors of the Consolidated Gas, Electric Light & Power Company of Baltimore, at a meeting of the board held today, ratified an agreement between their company and the Northern Maryland Power Company providing for the acquisition by the Consolidated company of the property and business of the Northern Maryland Power Company in the whole of Harford County, excepting the Fifth election district, which is contiguous to the Conowingo power development."

It was understood that the Baltimore company paid more than $500,000 for the property, which was acquired by the Philadelphia Electric during the fight. The contest is believed to have assumed the proportions it did, not because of the unimportant territory directly involved, but in anticipation of the electrification of the Pennsylvania Railroad and because of strategical motives with respect to future industrial development.

## Purchases and Mortgages

The United Gas Improvement Company has disposed of its controlling interest in the Burlington Light & Power Company of Burlington, Vt., to the People's Light & Power Corporation. The sale is in accord with the company's policy to dispose of isolated properties and to group its holdings in public utilities so as to permit of the most economical operation.

The Pennsylvania Edison Company of Easton, Pa., has been merged into the Metropolitan Edison Company of Reading. Both are General Gas & Electric Company properties.

A petition for the incorporation of a second group of small light properties in the proposed Southeastern Indiana Power Company has been filed with the Indiana Public Service Commission by C. T. DeHore, president of the DeHore Management Corporation. These are the Milroy Light & Power Company, which serves Blue Ridge, Moscow, Clarksburg, Andersonville and Richland; the Atwood-Burkit Light & Power Company and the Battleground Light & Power Company. (See Electrical World for May 19, page 1033.)

A petition has been filed with the Indiana Public Service Commission by the Greendale Water & Electric Company for leave to purchase the utility holdings in Greendale, Ind., of the A. D. Cook Company of Lawrenceburg, Ind., for $75,000.

Shelbyville, Ill., has turned a deaf ear to tentative offers to buy its municipal electric light plant understood to have been made by the Central Illinois Public Service Company and will rehabilitate its plant at a cost of approximately $100,000.

Purchase of the South Sioux City (Neb.) municipal electric light plant by the Sioux City Gas & Electric Company and the grant of a 25-year franchise will be submitted soon to a vote. The company, which has made an offer of $75,000 for the plant, will pay costs of the special election.

Application has been made to the New York Public Service Commission by John D. Holmes for consent to transfer his electric plant in Downsville, Delaware County, to the New York State Electric Corporation.

The Atlantic City Electric Company has taken over the operation of the electric plant of Greenwich Township, Gloucester County, N. J. The company paid the township $31,870 for the property.

The Staunton (Va.) City Council is considering sale of the city's electric plant to the Virginia Public Service Company, which also has a plant in Staunton. A series of alternative proposals have been submitted to the company.

An offer from the Virginia Electric & Power Company of $35,000 for the lines and franchise of the Tarboro (N. C.) electric plant has been refused by the city commissioners.

By an overwhelming majority, the voters of Milton, Fla., on May 15 approved the sale of the municipal electric plant to the Gulf Power Company for $65,000, granting the company also a 20-year operating franchise.

The Southwestern Light & Power Company has purchased the privately owned light and power plant and distribution system in Davidson, Okla.

The Oklahoma Gas & Electric Company has purchased the 13,000-kw. Belle Island generating station of the Oklahoma Railway Company in Oklahoma City. This transaction follows the recent leasing of this station by the Oklahoma Gas & Electric together with transmission lines owned by Oklahoma Railway Company.

Operating in Crescent City, Calif., the Mountain Power Company has applied to the Railroad Commission for authority to sell its properties to the Public Utilities California Corporation for $85,000.

The Smith River Power Company, operating in Del Norte County in northern California, has applied to the California commission for authority to sell, and the Public Utilities California Corporation for authority to purchase, the properties of the former for $23,200 in capital stock.

## Montefiore Foundation Essay Award for 1929

Announcement is made by the association of electrical engineers composed of alumni of the Institut Electrotechnique Montefiore, Liége, Belgium, that the triennial prize awarded by the Fondation George Montefiore for the best original treatise (not of a popular character or a mere compilation) upon the scientific advance of electricity and its technical application in all domains will be again bestowed next year. This prize represents the accumulated interest on 150,000 francs invested in Belgian funds at 3 per cent and will amount to 29,000 francs.

Essays submitted must have been written in the three years preceding the award. They may be either in French or English, signed or anonymous, and must be printed or typewritten, twelve copies to be furnished. Five Belgian and five foreign electrical engineers, under the presidency of the director of the Montefiore institute, form the jury. The last day for the reception of papers submitted will be April 30, 1929. Further details of the competition will be supplied by the secretary-general of the Association des Ingénieurs Electriciens sortis de Institut Electrotechnique Montefiore—L. Calmeau, 31 rue Saint-Gilles, Liége, Belgium.

## Summer School for Engineering Teachers to Be Repeated

The Summer School for Engineering Teachers, open to all such teachers in the United States and Canada, which was established by the Society for the Promotion of Engineering Education in 1927, is to continue its sessions during the coming summer. Two schools will be held—one for teachers of physics and the other for teachers of electrical engineering. As in 1927, when mechanics was the subject studied, the purpose will be to study the principles and methods of teaching rather than to review actual content of subject matter.

The session on teaching physics will be at the Massachusetts Institute of Technology under the directorship of Dr. S. W. Stratton, president. The session on electrical engineering will be at Pittsburgh under the joint auspices of the University of Pittsburgh and the Westinghouse Electric & Manufacturing Company. Dr. F. L. Bishop of the University of Pittsburgh, secretary of the S.P.E.E., and Prof. Charles F. Scott of Yale University, chairman of the society's board of investigation and coordination, will serve as co-directors of the Pittsburgh session of the school. Prof. H. P. Hammond, associate director of the society's investigation of engineering education, is in general charge of the schools. Both sessions will be of three weeks' duration and will begin soon after July 4.

## Applications Before Federal Power Commission

The Niagara Falls Power Company has applied to the Federal Power Commission for the right to use all treaty water at Niagara Falls. At present that company is using 19,725 sec.ft. of the 20,000 sec.ft. available. The remaining 275 sec.ft. is being used by various licensees on Eighteen-Mile Creek, between Lockport and Lake Ontario, where it is transported through the State Barge Canal. These licensees have announced their willingness to surrender their licenses. The water can be used to develop virtually twice the amount of power at the Falls that it is now producing.

As reported last week, L. E. Bryant of Roberta, Tenn., has applied to the commission for a preliminary permit covering a project on the Rock Castle and Laurel Rivers near the boundary of Kentucky and Tennessee. It is planned to build a dam 190 ft. high on the Rock Castle River one mile above its mouth, where 20,000,000,000 cu.ft. of water would be stored. The dam on the Laurel River is to be 150 ft. high and would store 7,000,000,000 cu.ft. The power houses are to be below each dam and will be interconnected. Under such a plan it is estimated that 28,600 hp. of primary power can be made available. It is the intention of the applicant to install 39,300 hp. The power is to be used at coal mines in the vicinity of the sites.

The Kassan Gold Company of Seattle has applied for a preliminary permit covering a development on the east side of Prince of Wales Island, Alaska. It is proposed to construct a dam at the outlet of Little Salmon Lake so as to provide 10,000 acre-feet of storage. It is planned to install 1,500 hp. and to build a transmission line 10 miles long to the applicant's mine.

The Red River Lumber Company of Minneapolis has filed two applications for preliminary permits covering developments on Horse Creek at a point near Pittville, Calif., and on Lost Creek near Cassel, Calif. At the former project it is planned to make available 1,200 hp. of primary power and at the latter 4,800 hp. of primary power.

The Interstate Public Service Company of Indiana has withdrawn its application for a license covering a 6,000-hp. project on the East Fork of the White River. The company took this action on the ground that the project was not economically feasible under present conditions.

Fred and John Dover, who have been operating a project at U. S. Dam No. 6 on the Muskingum River, Ohio, have applied for a license under the water-power act. The War Department lease under which they have been operating has recently expired.

The Truckee River Power Company has applied for a license covering the erection of 28 miles of transmission line to connect an existing line with Durkee, Idaho, and to connect Tahoe City to Brockway.

# Briefer News

WATERBURY STEAM STATION ABANDONED.—The Connecticut Light & Power Company, Waterbury, Conn., has abandoned its Waterbury power station, erected twenty years ago, and will get its power for that city entirely from its hydro-electric plants.

NEW UNIT GOES IN FOR GULF STATES UTILITIES TEXAS SYSTEM.—A 35,000-kw. turbo-generator was placed in operation last week at the Neches power station of the Gulf States Utilities Company of Beaumont, Tex., which serves a territory extending for more than 250 miles along the Gulf Coast. Transmission lines are nearly completed connecting 23 communities north of Houston to this base-load plant, which has been more than doubled in size.

FIGHT OVER ABSORPTION OF MARYLAND UTILITIES RESUMED IN COURT.—The Electric Public Utilities Company has renewed its suit for the vacation of the Maryland Public Service Commission's order refusing to grant it authority to purchase the stock of the Home Electric Company of Lonaconing, the Emmitsburg Electric Company, the Antietam Electric Light & Power Company and the Midland Electric Light Company, all Maryland corporations. The commission's action was recorded in the ELECTRICAL WORLD for May 5 (page 927.)

CINCINNATI RATE BILL PASSES COUNCIL.—Cincinnati's City Council has passed the new electric rate bill (ELECTRICAL WORLD, April 21, page 826), and it will go into effect on Sept. 1. It is designed to cut off from $500,000 to $600,000 of the Union Gas & Electric Company's net annual profit from electricity on the basis of present consumption. One councilman opposed the measure, asserting that the city should continue its fight in the federal courts to make effective the first new ordinance proposed, which was designed to cut off $750,000 net profit.

OREGON COMMISSION LACKS FUNDS FOR RATE INVESTIGATION. — Estimates thought conservative place the number of electrical engineers necessary for a state investigation of the valuations of the widely ramified properties of the Portland Electric Power Company and the Northwestern Electric Company at a minimum of fourteen, and the expense of such a probe would possibly reach an almost prohibitive sum. At the present time the Oregon Public Service Commission has for its engineering personnel one chief and one assistant, and the funds with which to operate the department until the Legislature again meets next January are about exhausted. The commission on its own motion has ordered that the valuations of the two Portland utilities be undertaken at once, but whether it will be able to carry out this program is said to be doubtful.

PORTLAND COUNCIL ENGAGES TACOMA ENGINEER TO VALUE PROPERTY OF PORTLAND ELECTRIC POWER COMPANY.—Kenneth G. Harlan, Tacoma (Wash.), utility engineer, has been retained by City Council of Portland, Ore., to evaluate the property of the Portland Electric Power Company with a view to obtaining revision of electric rates. Mr. Harlan will be paid a flat rate of $48,000, hiring his own assistants. The work must be finished by Dec. 15. The council will present the data gathered in a petition to the Public Service Commission for new rates.

RESTRICTIONS ON KLAMATH RIVER MAY BE RECONSIDERED BY VOTERS.—To determine whether the Klamath River can be used both for the maintenance of industrial plants and as a recreational and angling stream, a study is to be started in the near future under the leadership of the California Development Association. If the finding is that the dual use is feasible, it is probable that the voters will be called on by initiative to reconsider the vote by which in 1924 the river was declared closed to industrial and power development.

## *Coming Meetings*

[A complete directory of electrical associations, with their secretaries, is published in the first issue of every volume. For latest list see ELECTRICAL WORLD for Jan. 7, page 80.]

National Electric Light Association—Atlantic City, June 4-8. P. S. Clapp, 420 Lexington Ave., New York.

American Association of Engineers—Hotel Hussman, El Paso, Tex., June 4-6. M. E. McIver, 63 E. Adams St., Chicago.

National Electrical Manufacturers' Association—Radio Division, Chicago, June 4-7.

Electrical Supply Jobbers' Association—The Homestead, Hot Springs, Va., June 5-8. E. Donald Tolles, 165 Broadway, New York.

National Electrical Manufacturers' Association—The Homestead, Hot Springs, Va., June 11-15. S. N. Clarkson, 420 Lexington Ave., New York.

Artistic Lighting Equipment Association—Hotel Sherman, Chicago, June 11-16. G. P. Rogers, 420 Lexington Ave., New York.

Pacific Coast Division, N.E.L.A. — Hotel Huntington, Pasadena, Cal., June 12-15. S. H. Taylor, 447 Sutter St., San Francisco.

Georgia Electrical Association—Savannah, June 14 and 15. J. J. McDonough, Georgia Power Co., Dublin, Ga.

Northwest Division, N.E.L.A.—Portland, Ore., June 19-22. B. Snow, 1208 Spalding Bldg., Portland, Ore.

Canadian Electrical Association—SS. "Richelieu" from Montreal to Saguenay and return, June 20-23. H. M. Lyster, 712 Power Bldg., Montreal.

American Institute of Electrical Engineers—Cosmopolitan Hotel, Denver, June 25-29. F. L. Hutchinson, 33 West 39th St., New York.

Association of Iron and Steel Electrical Engineers—Hotel Stevens, Chicago, June 25-28. J. F. Kelly, Empire Bldg., Pittsburgh.

American Society for Testing Materials — Chalfonte-Haddon Hall, Atlantic City, N. J., June 25-29. C. L. Warwick, 1315 Spruce Street, Philadelphia.

East Central Division, N.E.L.A.—Cedar Point, Ohio, July 10-13. D. L. Gaskill, Greenville, Ohio.

Wisconsin Utilities Association, Electric Section—Appleton, Wis., July 26 and 27. J. N. Cadby, 432 Broadway, Milwaukee.

MORE INTERCONNECTION IN VIRGINIA.—Transmission lines of the Virginia Electric & Power Company will soon be extended 13 miles from Quantico to Occoquan, Va., connecting that point with the lines of the Virginia Public Service Company running south from Alexandria. The cost of the new extension is put at approximately $150,000. The line, to be completed probably by September, will carry 66,000 volts. Connections with the Virginia Public Service Company at Roanoke Rapids, N. C., will be made also.

TONAWANDA POWER COMPANY TO HAVE NEW OFFICE BUILDING.—Officers and directors of the Buffalo, Niagara & Eastern Power Corporation and the Tonawanda Power Company assembled at North Tonawanda, N. Y., on May 17 to take part in the ceremonies attending the laying of the cornerstone for an ornamental quarter-million-dollar two-story building to be occupied jointly by the Tonawanda Power Company and the State Trust Company. According to the designers, the lighting effects, exterior and interior, to be used for the new building will be "the best between New York City and Chicago."

HUGHES ELECTRIC WILL BUILD 225 MILES OF LINE IN NORTH DAKOTA.—Announcement that the Hughes Electric Company of Bismarck, N. D., will build 225 miles of transmission line during the summer of 1928, has been made by O. W. Mattison, new general manager of the company. Included will be a line from Beulah to Bismarck, a line connecting Elgin and Thunderhawk and a line from Sterling to Bismarck. The transmission expansion is in addition to plant improvements at Beulah increasing the plant capacity substantially. New-type boilers are being installed.

ARTISTIC LIGHTING EQUIPMENT CONVENTION.—In connection with an elaborate exhibition of lighting equipment to be held at the Sherman Hotel, Chicago, on June 11-16, by the Artistic Lighting Equipment Association, there will be a convention of that society, at which group meetings of manufacturers, distributors and dealers will be supplemented by open sessions. At one of these there will be a discussion on "meeting the problem of lower selling costs." At the first day's proceedings William R. Dawes, president of the Chicago Association of Commerce, will make an address.

SHAWINIGAN COMPANY CONTEMPLATES ADDING TO ITS RESOURCES.—It is likely that the Shawinigan Water & Power Company will soon increase its power resources in the Province of Quebec by the acquisition of sites having a total potential capacity of 500,000 hp. These sites are on the St. Maurice River above La Tuque. They are to be auctioned by the Quebec government on May 23, and it is conceded that Shawinigan will in all probability be the only bidder. It is altogether likely that the company will use these sites to serve the St. Maurice Valley territory or the more easterly sections of the Shawinigan system, rather than Montreal, which is about 250 miles from the additional source of power.

Duquesne Light Company Places Highland Substation in Operation.—Another substation has just been added to the chain of eight which serve Pittsburgh by stepping down 66,000-volt power from the Colfax generating station to 22,000 volts and then transmitting it to distribution stations. The new substation, known as the Highland, is rated at 30,000 kw. and is about nine miles from Colfax. At present only one circuit to it has been built, though it is designed for two. The connection necessitated an overhead crossing of the Allegheny River and the construction during the winter months of a steel-tower transmission line over rough, hilly country.

Work Starts on New Gorgas Unit for Alabama Power Company.—Construction work has started on the new Gorgas steam plant (Unit No. 4) of the Alabama Power Company, an announcement by the company says. Excavation will be completed in the early autumn. Steel erection is scheduled to begin about the middle of June and will be completed about the first of August. Condensers will be installed in October, the boilers in September and the turbines in December. The present schedule calls for completion of the plant about May 1, 1929. The plant will ultimately add 240,000 kw. to the Alabama Power Company's system in four units of 60,000 kw. each, of which the one under way will be the first.

Springfield, Mass., Going Ahead with City-Owned Hydro Plant.—Construction of the large dam and tunnel for the water system expansion and electric power development by the city of Springfield, Mass., in connection with its Little River supply will be started early this summer, according to present plans. A call for bids probably will be issued early in June. The water commissioners have authorized the city solicitor to make a contract with the Turners Falls Power & Electric Company for a lease of the power plant, at a rental price of $270,000 a year for 30 years (see Electrical World for Dec. 10, 1927, page 1216). A bond issue of $4,500,000 has been authorized by the city for the development.

Rate Reductions in Missouri and Arkansas.—Reductions in electric rates for residence consumers in 92 Missouri towns are provided in rate schedules filed with the Public Service Commission at Jefferson City, Mo., May 11 by the Missouri Public Service Company and the Arkansas-Missouri Power Company. Both have their headquarters in St. Louis and are controlled by the Insull interests. Power for industrial and commercial use is reduced in 30 of the towns under the new schedules. Similar reductions will be made in 27 towns in Arkansas served by the Arkansas-Missouri Power Company. The reductions in Missouri range from 5 to 25 per cent and approximate $100,000 annually. Prior to May 11 the Missouri Power & Light Company reduced rates affecting 94 towns and aggregating $127,000 and the Maryville Electric Light & Power Company cut its rates in Maryville.

Right of Owner of Apartment House to Retail Energy to Be Tested in Brooklyn.—Whether a landlord can compel the Brooklyn Edison Company to furnish energy wholesale to an apartment house so that electricity may be retailed to tenants instead of permitting them to deal with the electric company directly will be determined in a suit filed last week in the New York Supreme Court. The owner asserts that under rulings of the Public Service Commision a landlord has a right to buy energy at wholesale and retail it. He alleges that the electrical equipment in his apartment building is valued at $30,000 and that representatives of the Brooklyn Edison Company have notified him that they intend to deal with the tenants directly or else remove the meters from the building and suspend service for all purposes.

Indianapolis Company Completes New Administration Plant.—Centralization of the service operations of the Indianapolis Power & Light Company is made possible with the completion of a new million-dollar plant on Morris Street, covering a fourteen-acre tract. Officials of the operating and engineering departments have just moved into the three buildings composing it, which have been in course of construction for about two years. These are an administration building, with a storage building and a garage on either side. All are of brick and concrete. They house five hundred men and women. The administration building is one of the most complete of its kind. On the lower floor is a large lecture room with club facilities for employees.

Remodeling of Cahokia Station Includes New 75,000-Kw. Turbine.—The Union Electric Light & Power Company of St. Louis has made plans to

## New York Edison Adopts New Coal-Hoisting System

A NEW coal-hoisting system that unloads coal directly from ocean-going vessels into the power generating station of the New York Edison Company on the East River at Thirty-eighth to Fortieth Street has been put into operation with the unloading of the Pocahontas Steamship Company's collier *Bristol* from Norfolk. The effect of the new system, an official of the New York Edison Company said, is to broaden the company's coal market, so that now coal may be obtained either by oceangoing colliers or by rail. Moreover, by the new system coal can be unloaded from moored colliers into barges for transport to the other power-generating plants owned by the company.

In the new system the bucket hoist is only 60 ft. The clamshell buckets place the coal on belt conveyors, one of which is 395 ft. long, for the remaining elevation of 100 or more feet to the bunkers. These long conveyors reach out to 30-ft. deep water, where ocean-going vessels can be moored. Two steel towers for hoisting the grab buckets travel on rails, permitting the buckets to be dropped into the various hatches without moving the vessel. The two buckets have a capacity of 350 tons an hour each. The *Bristol*, the first collier to be unloaded by the new system, carried 6,600 tons.

remodel and expand its Cahokia station, on the Illinois side of the Mississippi. The plans include the installation of a 75,000-kw. General Electric turbo-generator. Space for it will be provided by removing a 30,000-kw. machine. Foundations will be strengthened to suit the larger unit and the condenser altered. The unit which is removed will be installed in the Venice station of the company, adjacent to Cahokia. The new turbine will be a single-cylinder, 1,800-r.p.m. machine receiving steam at 315 lb. gage, 300 deg. superheat, and will operate against a back pressure of 1 in. absolute. The generator will be rated at 60 cycles, 13,800 volts, three-phase, and 90 per cent power factor.

New Offer for Purchase of Elephant Butte Power.—The Texas-Louisiana Power Company has submitted a proposal to the boards of directors of the irrigated districts of the upper Rio Grande Valley for the development and utilization of electric power from the Elephant Butte reclamation dam in New Mexico. There is already pending before the boards of directors a similar proposal from the El Paso Electric Company. The proposal of the Texas-Louisiana company is to construct and operate a hydro-electric plant at the dam and pay to the water users a minimum of $86,000 yearly with no investment on their part. The $86,000 would be based on an output of 40,000,000 kw.-hr. or less, and in addition $6,000 would be paid for each 5,000,000 kw.-hr., extra up to 68,000,000 kw.-hr., after which the company would pay 1¼ mills additional for each kilowatt-hour generated at Elephant Butte Dam. The proposed contract between the irrigation districts and the Stone & Webster interests, which control the El Paso Electric Company, is based on construction by the water users of the hydro-electric plant at the dam. The El Paso company would then purchase the energy, for which it would pay an annual minimum charge of $180,000 for 36,000,000 kw.-hr. The districts would have to issue bonds to raise money with which to build the plant.

Water-Power Site Filings in Oregon.—Albert Anderson of Grant's Pass, Ore., has filed an application with the State Engineer for a permit to construct a reservoir for the storage of 18,700 acre-feet of water from the South Fork of the Coquille River and to appropriate 75 sec.-ft. of such stored water and the natural flow of the river for the development of 13,261 theoretical horsepower. The site is in Coos County, the operating field of the Mountain States Power Company, which maintains priority rights. An application was filed also by W. E. Green, Portland, for a permit to appropriate 2,500 sec.-ft., from the Deschutes River in Sherman County for the development of 420,000 theoretical horsepower. This site is in territory now served by the Deschutes Light & Power and the Pacific Light & Power Companies. E. G. Hopson of Portland has filed application for a permit to appropriate 5,000 sec.-ft. of water from the Deschutes River for the development of power in Sherman County. A. L. Shreve of Mapleton has filed on waters in Berkshire Creek for light and power development purposes in Lane County, and D. P. Slater of Dallas asks permission to appropriate water from Rock Creek for power supply in Lincoln County.

Tennessee Commission Valuation Contested.—Valuation by the State Railroad and Public Utilities Commission of Tennessee of the Tennessee Eastern Electric Company at $2,500,000 and of its subsidiary the Johnson City Traction Corporation at $225,000 is being contested in the Circuit Court at Nashville by the utilities, which claim a joint value of $6,695,000. A special commissioner appointed by the court has placed the value at $3,500,000. He rates the physical value of the hydro-electric developments and the steam plant of the petitioners at $2,925,000. The companies claimed a "water-power value" of $2,000,000, which the commission refused to recognize at anything, but which Commissioner Kirkpatrick set at $200,000. The companies claimed a "going value" of $750,000 which the commission set at $240,000 and the Kirkpatrick report raised to $275,000. Commissioner Kirkpatrick allowed a "working capital" of $100,000, but agreed with the state authorities in refusing any allowance for "cost of financing and organizing" and "added risk in developing."

## Commission Rulings

Customer-Owned Meters Excluded from Rate-Fixing Valuation.—A former rule of the Colorado Public Utilities Commission requiring utilities to own and maintain meters and incidental connections has been permanently suspended by it, with the express restriction that such equipment owned by consumers shall not be valued as useful utility property in any valuation for rate-making purposes.

Consumer Has No Right to Hamper Regular Reading of Meter.—Although holding that discontinuance of service to enforce the payment of a bill disputed in good faith is not justified until the question of indebtedness has been settled in a court of law, the New Jersey Board of Public Utility Commissioners blamed a customer of the Public Service Electric & Gas Company for rendering it difficult for the company to make regular monthly meter readings, saying: "This case differs from the usual complaints received by the board in that the meter, through the fault of the complainant, was not read monthly. If the readings had been made monthly, the trouble might have been averted. The testimony shows that the complainant's house was frequently closed when the meter reader called and that regular readings were impossible; also it appears that the complainant is the owner of several police dogs, which he keeps on the premises, and warned the meter reader to beware of them. The company is fairly entitled to have the meter at complainant's premises read monthly by its meter reader. It cannot be reasonably expected to make a special or unusual effort to obtain readings. If the complainant refuses or neglects to maintain a condition at his residence admitting of regular meter readings without hazard or threat of same to the reader, the company will be justified in discontinuing service and refusing to resume the supply until such condition is corrected."

## Recent Court Decisions

Company Responsible for Injury to Boy Who Climbed Father's Tree, Through Which Company's Wire Ran.—Damages were affirmed in Anstead vs. Pacific Gas & Electric Company by the Supreme Court of California. This suit was brought because of injury to a nine-year-old boy who climbed a tree on his father's ranch to pick apples and came in contact with a high-tension wire belonging to the company and passing through the tree. The allegation that it was the custom for power companies to run their wires through fruit and shade trees did not excuse the defendant, the court said, unless this practice was shown to be consistent with due care. The accident itself showed that the insulation was not sufficient. The boy had a right to be in the tree. Errors in the admission of evidence had not prejudiced the case, the court held also, and the verdict for $15,000 for permanent injury was not excessive as a matter of law. (265 Pac. 487.)*

Supreme Court Finds Special Tax for Recording Long-Term Mortgages Unconstitutional.—A tax of 20 cents upon each hundred dollars of mortgage indebtedness recorded in Kentucky where the indebtedness does not mature within five years has been declared unconstitutional by the United States Supreme Court in Louisville Gas & Electric Company vs. Coleman, State Auditor, and it has reversed the action of the lower court in sustaining the law. "It seems clear," the Supreme Court says, "that a circumstance which affects only taxable values has been made the base of a classification under which one is compelled to pay a tax for the enjoyment of a necessary privilege which—aside from the amount of the recording fee which is paid by each—is furnished to another as a pure gratuity. Such a classification is arbitrary. . . . The effect is to deny plaintiff the equal protection of the law in violation of the equality provision of the Fourteenth Amendment." In a dissenting opinion by Justice Brandeis, concurred in by Justices Holmes and Stone, it was said: "There is abundant proof that the Legislature was justified in thinking that the bulk of the long-term loans would escape the general property tax, while most of those for a short term would not. . . . The equality clause would not prevent a state from confining the recording tax to deeds of trust given to secure bonds of a public service corporation. . . . If the statute as applied does not in fact discriminate in favor of any property of a like nature, there is not inequality in treatment."

# News About Men of the Industry

## *Dwight Heads Boston Section A.I.E.E.*

Prof. H. B. Dwight of the Massachusetts Institute of Technology was elected chairman of the Boston section of the American Institute of Electrical Engineers at the annual meeting last week, the new vice-chairman being Wellen H. Colburn of the Edison Electric Illuminating Company of Boston and the secretary and treasurer George J. Crowdes of the Simplex Wire & Cable Company, Boston.

ELMER A. SPERRY, chairman of the board of directors of the Sperry Gyroscope Company, Brooklyn, N. Y., was nominated for the presidency of the American Society of Mechanical Engineers at a recent meeting of the nominating committee held at Pittsburgh, Pa., during the spring meeting.

NICHOLAS M. DU CHEMIN has been placed in charge of the West Lynn works of the General Electric Company during the illness of Frank P. Cox, manager. Mr. Du Chemin has been in the employ of the company for nearly fifteen years, having passed through the company's apprentice course at the River Works, Lynn, Mass., and risen to the post of general superintendent at West Lynn. The many friends of Mr. Cox in the electrical industry will be glad to learn that he is on the road to full recovery.

M. V. WATSON, manager of the Arizona Power Company, Prescott, Ariz., for seventeen years, has been appointed general manager of the Peoples West Coast Hydro-Electric Corporation, Portland, Ore. Mr. Watson's early experience was obtained in the employ of electrical contractors of Kansas City, Mo., and the U. S. Reduction & Refining Company's plant in Colorado Springs. Subsequently he served as superintendent of the Guanajuato Power Company's plant in Zamorra, Mexico, and in the engineering department of the Central Colorado Power Company, Denver.

JOHN W. LIEB, vice-president of the New York Edison Company, sailed for Europe, May 19, aboard the liner *Hamburg*. His first objective will be England, where he is planning to obtain a much-needed rest. While in London Mr. Lieb, as an official delegate of the American Institute of Electrical Engineers, will attend the centenary of the Institution of Civil Engineers (British). Later he will attend the inauguration of the Library, University of Louvain, as an official delegate of the American Engineering Societies, during which there will be presented the clock and carillon, the gift of the Engineering Foundation. Before returning to New York Mr. Lieb will visit Paris and as vice-president and representative of the National Electric Light Association attend the meeting of the International Union of Producers and Distributors of Electrical Energy. Mr. Lieb will arrive in New York late in July.

## *R. T. Smalley President of Middle West Division*

R. T. Smalley, who was elected president of the Middle West Division of the National Electric Light Association at its recent convention in St. Louis, Mo., as announced in the May 19 issue of the ELECTRICAL WORLD, is vice-president of the Kansas Electric Power Company with headquarters at Lawrence, Kan. Mr. Smalley is a graduate of the College of Emporia and entered the employ of the Kansas Electric Power Company in 1919 as meter reader and repair man. He later became assistant manager of the Emporia district and in 1921 was transferred to the Parsons, Kan., district of the same company. In 1923 he returned to Emporia as district manager and in 1926 was transferred to the general offices of the company at Lawrence as assistant general manager. Early this year Mr. Smalley was elected a vice-president of the Kansas Electric Power Company. He has been an active figure in association work in Kansas, directing his attention especially to the Kansas Public Service Association, the Kansas Section and the Middle West Division of the National Electric Light Association and the Information Bureau of Kansas Public Service Companies.

*R. T. Smalley*

RAY BAUMGARDNER of Dallas has been appointed director of public information for the Central & Southwest Utilities Company to succeed the late George McQuaid. Mr. Baumgardner has been state manager of the Associated Press for the past seven years. In his new position he will be responsible for the direction of information services of several operating companies in Texas, Oklahoma and Arkansas, including the Southwestern Gas & Electric Company, the Central Power & Light Company and the West Texas Utilities Company.

H. EDMUND MACHOLD, president of the Northeastern Power Corporation, has been elected president of the Northern New York Securities Corporation, Watertown, N. Y.

# Obituary

JAMES W. BULLOCK, until several years ago an officer of the Bullock Electric Manufacturing Company, Cincinnati, died May 9 at his home in that city following two weeks' illness of pneumonia. Though an officer and director of a number of Cincinnati corporations at the time of his death, Mr. Bullock retired from active business about two years ago.

ROY B. MCPHERSON, general superintendent of the electrical department of the Utica (N. Y.) Gas & Electric Company, died at his home in that city May 14 after a short illness. Mr. McPherson was born in New York Mills, N. Y., in 1894. In 1915 he became associated with the Utica Gas & Electric Company, eight years later being made acting assistant superintendent. In 1924 he was named general superintendent.

CHARLES W. MULLEN, at one time a member of the Public Utilities Commission of Maine, died at his home in Bangor, May 18. Following graduation from the University of Maine in 1883, he entered upon a career that embraced railroad building, the development of hydro-electric power and the construction of pulp and paper mills in New England and Canada. Mr. Mullen was also prominent politically, having been Mayor of Bangor in 1911 and 1912 and a former state senator.

DALE PETERS, manager for the Southern California Edison Company at Huntington Beach, Cal., died May 7 from the effects of an apoplectic stroke, sustained while playing golf. Mr. Peters had been manager at Huntington Beach for more than four years.

DONALD KEMP PROSSOR, an electrical engineer attached to the Pittsfield (Mass.) Works of the General Electric Company, was accidentally killed recently at Durham, N. C., by an electric shock received on a construction job for the Carolina Power & Light Company. He was 29 years of age, a graduate of New York University in 1921 and was favorably known through his connection with the 132-kv. cable installation lately made in New York City.

# Financial and Statistical News

## *Market Prices Recover Several Ten-Point Losses*

POWER and light stocks participated very actively in the sharp market decline which brought averages down several points this week from previous high levels. Although losses were not as heavy among utility stocks as in some other groups, ten-point losses during the decline were not at all exceptional, while fifteen and twenty-point declines took place in isolated cases. With the combination of high money rates and the reaction from an unusually buoyant market the previous week, the stage was in every way set for a successful bear movement and the one which took place was the most important selling movement for some months.

Among the stocks which reacted sharply from recent high prices were American Gas & Electric, Southeastern Power & Light, Public Service of New Jersey, Philadelphia Electric, Pacific Gas & Electric, Brooklyn Edison, Middle West Utilities. Utility stocks, however, were among the first to recover after the selling movement.

## Two New German Loans Floated

Twenty-year 6 per cent gold sinking fund debentures of the Allgemeine Elektricitäts Gesellschaft (General Electric Company, Germany) have just been offered to the amount of $10,000,000, the price being 94½ and interest to yield 6.50 per cent. These debentures were dated May 1, 1928, and mature May 1, 1948.

A five-million-dollar offering was made by the Unterelbe Power & Light Company (Elektricitätswerk Unterelbe, Aktiengesellschaft) in the form of 25-year 6 per cent sinking fund mortgage gold bonds, priced at 93 and interest to yield over 6.55 per cent.

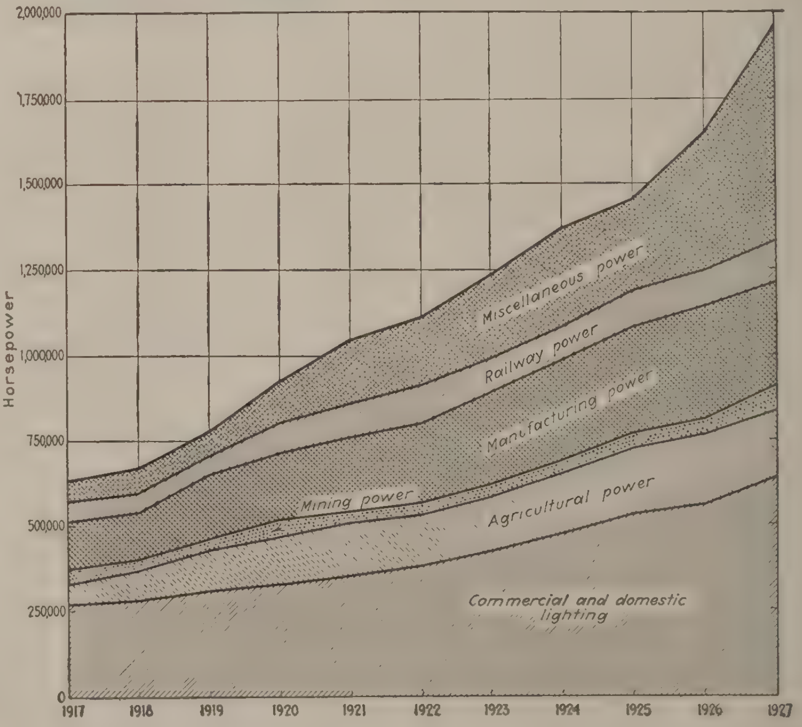
RECENT LISTINGS.—The New York Stock Exchange has authorized the listing of 532,000 additional shares of common stock of the Engineers Public Service Company on official notice of issuance in exchange for bankers' interim receipts for $5 dividend preferred stock, or in exchange for $5 dividend preferred stock when issued, making the total amount applied for 1,649,905 shares. The New York Exchange has also authorized the listing of 1,127,459 shares of common stock of the Pacific Lighting Corporation without par value and of $5,482,850 additional common stock (par $25) of the Southern California Edison Company, making the total amount applied for $56,807,050. The securities of foreign companies were also authorized for listing. Refunding gold bonds of the Norwegian Hydro-Electric Nitrogen Corporation were authorized for listing to the amount of $20,000,000 and first mortgage sinking fund bonds of the Shinyetsu Electric Power Company, Ltd. (Japan) were authorized for listing to the amount of $7,650,000.

NEW CINCINNATI GAS ELECTS DIRECTORATE.—Following the consummation of the merger of the Columbia Power Company, the Cincinnati Gas & Electric Company and the Union Gas & Electric Company into a new company called the Cincinnati Gas & Electric Company, Charles D. Jones, president of the old Cincinnati company, was elected chairman of the board of directors. The following directors have been elected: Samuel Assur, H. C. Blackwell, Alfred C. Cassatt, Fred W. Crawford, W. W. Freeman, Philip G. Gossler, James M. Hutton, Charles D. Jones, Polk Lafoon, Lawrence K. Langdon, John C. Pew, Edward Reynolds, Jr., Charles P. Taft and Frank M. Tait.

## Pacific Gas & Electric Earns $2.66 on Common

CONCENTRATED into the prosperous and rapidly developing upper half of the state of California, Pacific Gas & Electric System has shown a steady annual growth in earnings to last year's $54,719,227 gross. The system has followed the policy of absorbing the properties of smaller companies until its plants and properties, with those of closely affiliated companies, today stand at the huge total of $300,434,894.

Last year's financial progress involves a 7.4 per cent rise in gross revenues and an 18.5 rise in net income. Operating costs and maintenance, taken jointly, were held practically unchanged over the previous year. The operating ratio was reduced from 57 in 1926 to 53 last year. Furthermore, the balance available for common stock was 30.4 per cent greater than in 1926, although dividends required by preferred stock were up about half a million. The balance after common stock was up almost 70 per cent. The company pays $2 on its $25 par common stock, or 8 per cent. Earnings last year on common amounted to $2.66, against $2.54 in 1926. At a current price of around $50 the stock is worth about nineteen times earnings, which is somewhat above the average. The system's property investment is about $5.45 per dollar of gross revenue. Bond interest was earned 2.8 times. Interest charges have been earned at least twice for the past fourteen years.



*Growth of connected load in horsepower*

### TEN YEAR ANALYSIS OF GROWTH

| | Actual Increase | Percentage Increase |
|---|---|---|
| Gross revenue | $34,905,846 | 176.17 |
| Electric sales (kw.-hr.) | 1,070,821,000 | 182.38 |
| Gas sales (cu.ft.) | 11,676,909,000 | 136.77 |
| Consumers | 517,060 | 37.927 |
| Stockholders | 37,927 | 465.88 |

Large investors today thoroughly examine the background of a company in which they propose to invest. Pacific Gas & Electric checks up very satisfactorily in this regard. A ten-year analysis shows the growth as given in the accompanying table.

Hartford Utility Changes Set-Up. — Stockholders of the Hartford Electric Light Company have approved a reduction in par value of the stock from $100 to $25 and an increase in shares from 180,000 to 720,000. The directors have been authorized to issue 80,000 shares of $25 par stock in substitution for the authority to issue 20,000 shares of $100 par value granted in February.

## New Capital Issues

During the week ended May 24 the Allied Power & Light Corporation issued 150,000 shares of first preferred stock, $5 series, each share being accompanied by one share of common stock. Proceeds from the sale of this first preferred stock, together with the proceeds from the sale of preference stock and common stock, will be used in the acquisition of stock interests in and other assets of companies acquired and for general corporate purposes.

The American Gas & Power Company, which last week made an offering of gold debentures, issued 40,000 shares of first preferred stock, $6 series, at $96 a share and accrued dividends, to yield 6.25 per cent. Proceeds from the sale of this stock and the gold debentures referred to will be used to reimburse the company in part for the cost of its holdings.

Two additional offerings of the Texas-Louisiana Power Company were made during the week under review, one in the form of fifteen-year 6 per cent sinking fund gold debentures and the other in the form of 7 per cent cumulative preferred stock. The debentures totaled $1,700,000 and the stock $1,000,000. Proceeds are to reimburse for improvements and for general corporate purposes.

Buffalo Utility Elects New Directors.—At the annual meeting of the Buffalo, Niagara & Eastern Power Corporation Lewis G. Harriman, Walter W. Huntley and Hans Schmidt were elected directors to fill vacancies.

New York Power & Light Reclassifies Stock.—At a meeting of the stockholders of the above company a resolution was adopted reclassifying the capital stock of the company to provide for the elimination of the 30,000 shares of 8 per cent preferred stock authorized and to increase the authorized $6 preferred stock by 30,000 shares. The outstanding 8 per cent preferred was called for redemption Jan. 1, 1928.

Connecticut Power Splits Shares. —Stockholders of the Connecticut Power Company have ratified the change in common stock from 60,283

## Stock Quotations of Electric Light and Power and Manufacturing Companies

(Prices on New York stock market unless otherwise noted. Unless otherwise noted the par, stated, or preference value of stock is $100.)

shares of $100 par value to 241,132 shares of $25 par value and the distribution of four new shares for each share now held. They also voted to authorize the creation and issuance of 120,000 additional $25 par common shares to be sold to common stockholders of record May 8 at par in the ratio of one new share for each five shares held.

CONSUMERS POWER ELECTS NEW DIRECTORS.—At a meeting of the board of directors of the Consumers Power Company R. P. Stevens and T. A. Kenney were elected members of the board.

MASSACHUSETTS LIGHTING ELECTS NEW TRUSTEES.—Philip Young of the banking house of Baker, Young & Company, Boston, and George F. Howland, treasurer of the Massachusetts Lighting Companies, were elected trustees of the last-named organization at the recent annual meeting in Boston. Philip Childs and Henry I. Harriman were re-elected trustees.

METROPOLITAN EDISON STOCK ON NEW BASIS.—The Metropolitan Edison Company declared a quarterly dividend of $2 a share on the common stock payable March 24 to holders of record March 15. This places the stock on an $8 basis, compared with $7 previously.

JAPAN UTILITY TO REFUND.—The Tokio Electric Light Company is planning a refunding operation that will involve $24,000,000 by offering new securities, proceeds from the sale of which will be used to retire 6 per cent notes maturing in August. Part of the issue will be offered in Japan.

NIAGARA UTILITIES PREPARE FOR MERGER.—The Tonawanda Power Company, the Niagara Falls Power Company and the Niagara, Lockport & Ontario Power Company have called their outstanding preferred stocks. The class A and class B preferred stocks of the Tonawanda company will be redeemed July 2 at $27.50 and $25.50 a share and accrued dividends; the Niagara, Lockport & Ontario preferred will be redeemed June 30 at $26.25 a share and accrued dividends and the Niagara Falls preferred will be redeemed on June 30 at $27.50 a share and accrued dividends. Holders of these various stocks may exchange them until June 1 for first preferred stock of for Buffalo, Niagara & Eastern Power Corporation, with which company the other companies are presently to be merged.

## The Electrical Industry in Europe

Per capita expenditures for electrical goods and estimates of energy generated—in most instances during 1925—in various European countries have recently been published by the Department of Commerce and are here reproduced. The figures were obtained from the Documentation on the Electrical Industry at the Geneva Conference of 1927.

PRODUCTION OF ELECTRICITY IN EUROPEAN COUNTRIES

| Country | Per Capita, Expenditure for Electrical Goods | Generation of Electrical Energy Annually, Millions of Kilowatt-Hours |
|---|---|---|
| Germany | $6.72 | 22,000 |
| France | 2.31 | 9,800 |
| Belgium | 2.52 | 1,700 |
| Great Britain | 6.26 | 11,000 |
| Italy | 1.02 | 7,600 |
| Spain | 0.86 | * |
| Netherlands | 1.26 | 900 |
| Switzerland | 4.90 | 3,900 |
| Austria | 3.48 | 1,600 |
| Czechoslovakia | 1.33 | 850 |
| Hungary | 1.10 | 710 |
| Russia | 0.14 | 4,100 |
| Poland | 0.23 | 1,300 |
| Finland | 1.95 | 233 |
| Sweden | 2.64 | 3,500 |
| Norway | 2.69 | 6,200 |
| Denmark | 2.00 | 350 |

* No statistics available.

Public Service to Double Preferred Shares.—The Public Service Corporation of New Jersey has called a special meeting of stockholders for May 28 to vote on a proposed increase in the authorized preferred stock from 2,000,000 shares to 4,000,000 shares, the additional shares to be no-par $5 dividend stock. This is the first preferred stock issue of the company without par value. The preferred stock now authorized consists of 250,000 shares of 8 per cent cumulative preferred, 500,000 shares of 7 per cent cumulative preferred and 1,250,000 shares of 6 per cent cumulative preferred stock, all of $100 par value. There are also 10,000,000 shares of no-par common stock authorized.

Ingersoll-Rand Extra Dividend.—The Ingersoll-Rand Company recently declared an extra dividend of $1 in addition to the regular quarterly dividend of 75 cents on the common stock.

# World's 33,000,000 Hydraulic Horsepower

The developed water power of the world, according to estimates of the U. S. Department of the Interior through the Geological Survey, was about 23,000,000 hp. in 1920, 29,000,000 hp. at the end of 1923 and 33,000,000 hp. at the end of 1926, an increase of 43 per cent in six years. About three-fourths of the increase for the last three years has been in the English-speaking section of North America.

The estimates here given are considered sufficiently accurate to afford a rough idea of the potential water-power resources of the world and the extent of their development, although it is difficult to co-ordinate estimated water power for the several countries, particularly estimates of potential water power, because of differences in their elements and character and in the completeness and accuracy of the data on which they are based. The figures for the developed water power represent the rated capacity of waterwheels or turbines installed, and the figures for the potential power represent the total power that could be obtained at ordinary low water, including the power already developed. The installed capacity usually amounts to two or three times the power available at low water.

TABLE I—THE WORLD'S WATER POWER BY CONTINENTS

| Continent | Developed Horsepower | Potential Horsepower |
|---|---|---|
| North America | 16,800,000 | 66,000,000 |
| South America | 750,000 | 54,000,000 |
| Europe | 13,100,000 | 58,000,000 |
| Asia | 2,100,000 | 69,000,000 |
| Africa | 14,000 | 190,000,000 |
| Oceanica | 240,000 | 17,000,000 |
| Approximate total | 33,000,000 | 454,000,000 |

The figure for the developed water power in the United States includes only plants having a capacity of 100 hp. or more and is based on excellent data; the corresponding potential power is the amount available 90 per cent of the time at 70 per cent efficiency.

*Table II—Summary of Potential and Developed Water Power in 1926, by Countries*

(Estimated by the United States Geological Survey)

| Country | Developed Horsepower | Potential Horsepower |
|---|---|---|

## Operations Materially Increase During April

### Rate of Production in Electrical Manufacturing Plants 18 per Cent Over April of Last Year—Smaller Manufacturers Report 16.4 per Cent Gain During April Over March

During April the electrical manufacturing plants of the nation reported that productive operations as indicated by the consumption of electrical energy were materially above those of March and only slightly below the record peak of activities recorded in October last year. A radical upward turn in the rate of operations in these plants was hardly to be expected at this season of the year, if the operations of past years is to be taken as a criterion. April rate of operations, after corrections are made for the number of working days, was about 11 per cent above that reported for March and about 18 per cent above that of April last year. The average rate of operations of these electrical manufacturing plants during the first quarter of the current year was about 5 per cent above that for the same period last year.

The smaller electrical manufacturing plants reported a much greater increase in rate of operations during April than was reported by the larger companies. The April rate of production by the smaller plants was 16.4 per cent over that of March, a large number of these companies reporting a greater consumption of electrical energy during April than during March, in spite of the fact that April had two less working days than March. The larger companies reported a rate of production during April only 1.4 per cent above that of March.

The index of activity in the electrical manufacturing industry based on the consumption of electrical energy stands at 128.4 for April, as compared with 115.3 for March and 131.3 for the record month of October, 1927. Comparative indexes of productive activity referred to the average productive activity for the period 1923-25 as 100, and adjusted for number of working days, are as follows:

| | |
|---|---|
| April, 1928 | 128.4 |
| March, 1928 | 115.3 |
| February, 1928 | 121.8 |
| October, 1927 (peak month) | 131.3 |
| April, 1927 | 108.9 |
| April, 1926 | 107.8 |

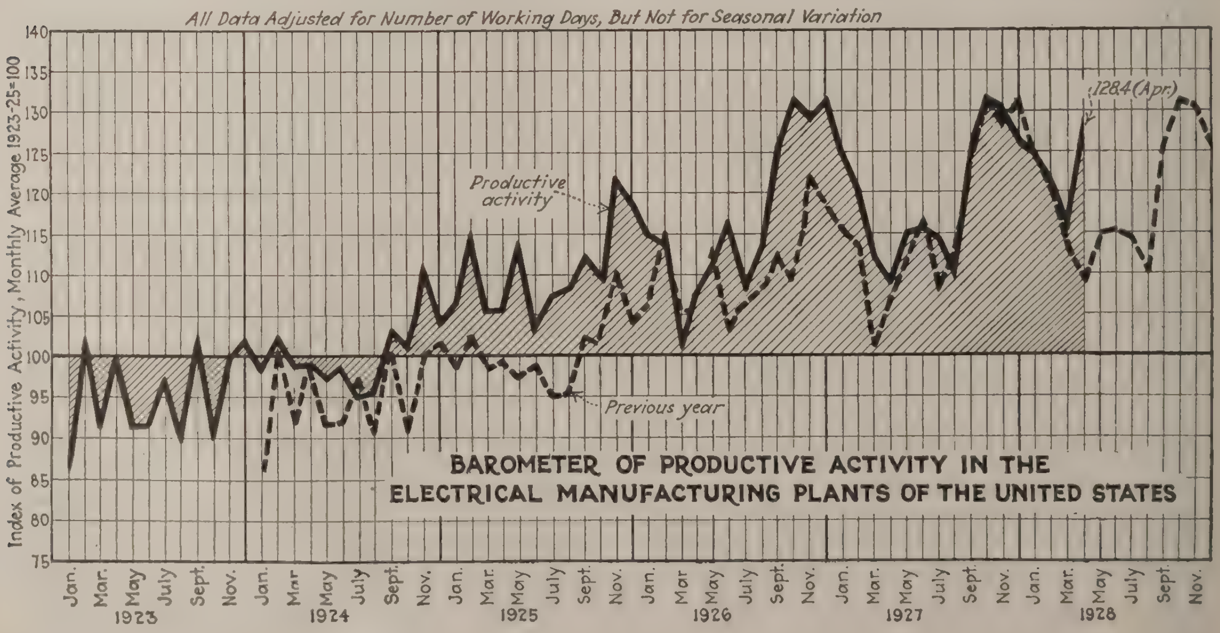
General industry also recorded an upward swing in the rate of operations during April. The April rate of general industrial operations for the country as a whole was close to 1 per cent greater than that witnessed in March and was about 2.2 per cent over April of last year. Industrial operations are being well sustained, some of the outstanding industrial groups recording increased operations, when a slight seasonal decrease would be expected normally. The favorable industrial situation is reflected by the fact that during the first four months of the current year the average rate of activity of general industry was about 3.7 per cent above that during the same period in 1927.

## Building Industry to Stabilize Credit Conditions

To correct improper practices and to stabilize credit conditions in the building construction industry, representative sub-contractors and general contractors have joined in the Allied Construction Industries Committee, a new body recently formed at a meeting in Washington, D. C. Members of the committee, representing thirteen national associations, are to meet at Detroit next month to advance the work already accomplished and to give a more definite form to the program for future activities. The organization includes members of the executive committee of the Associated General Contractors of America and two representatives from a number of trade organizations including the Elevator Manufacturers' Association and the Association of Electragists, International.

George B. Walbridge, Detroit, former president of the Associated General Contractors of America and chairman of the committee, presided at the organization meeting and submitted a report of that session to the full conference.

In addressing the conference, Mr. Walbridge declared "hundreds of concerns operating in the construction industry are in a state of perpetual insolvency. They secure materials and



equipment under loose credits, reaping their profits by failure to pay their bills and by using inferior materials and workmanship." Foremost among the measures to be given consideration at the Detroit meeting next month will be the formulation of rules of ethical practices. Establishment of a rational credit system also will be undertaken as a primary move.

# Market Conditions

SLOW but steady progress is registered by the electrical industry so far in 1928, although sales have been spotty in some districts. In fact, some manufacturers have even termed business as slow, yet they are optimistic. There appears to be a definite trend to greater activity on the part of industrial plants, and much electric railway business is in sight. The inquiries in the market and the active projected business bear out an optimistic feeling.

In New England the sales volume is expanding. A number of orders for heavy industrial equipment are pending. Industrial business is becoming more active in the Eastern district. Major industrial projects include a cement mill in Ohio, to cost $1,000,000; an automobile assembling plant in Missouri, to cost $1,500,000; an aircraft plant in Ohio, to cost $1,200,000. A soap manufacturer in Baltimore plans the purchase of considerable equipment for a factory to cost $3,000,000. Central-station purchases are limited to immediate requirements. Volume of business as well as prospects look good in the Southeast district. An order was placed for oil circuit breaker equipment amounting to $40,000. A central-station company closed a contract for 45 electric refrigerators for an apartment house installation, while many street-lighting projects are reported. A slight improvement is noted in the St. Louis district. Better business is reported in the Middle West. Maintenance purchasing of central-station companies are quite heavy. A prominent utility company is buying at the rate of $92,000 per day. On the Pacific Coast a good deal of construction work is planned, although buying is comparatively slow. A large paper plant will be built in Port Townsend, Wash., at a cost of $3,000,000.

## *Non-Ferrous Metals Strong in Sellers' Market*

Metal producers are well satisfied with the trend of the market during the last week. Copper sales have dropped off to close to average in the domestic market, but the price has advanced and sellers have little to offer. Zinc has been exceedingly quiet, but the metal is so firmly held that prices have advanced a few points further. Lead and tin prices show little change, but the activity in each of these metals has been greater than last week.

NEW YORK METAL MARKET PRICES

| | May 16, 1928 Cents per Pound | May. 23, 1928 Cents per Pound |
|---|---|---|
| Copper, electrolytic..... | 14.15–14.175 | 14.375 |
| Lead, Am. S. & R. price | 6.10 | 6.10 |
| Antimony.............. | 11⅛ | 11.125 |
| Nickel, ingot............ | 35 | 35 |
| Zinc spots.............. | 6.40 | 6.475 |
| Tin, Straits............. | 52¾ | 51.625 |
| Aluminum, 99 per cent... | 24.30 | 24.30 |

Base copper wire price May 23, 1928, 16⅜ cents.

## *Volume of Business Increasing in the Southeast*

While the past week witnessed an increase in the volume of small business in the Southeast, a few large orders were reported. One order was for oil circuit breaker equipment amounting to $40,000. An order for three 500-kw. and six 150-kw. transformers will probably be placed shortly. A central-station company closed a contract for 45 electric refrigerators for an apartment house installation, while another company has closed twelve apartment house jobs ranging from six to 24 units per installation, and several other similar installations are pending.

A cotton mill in Georgia will build an addition to its warehousing facilities and a contract will probably be let within a few weeks. Wiring supplies aggregating $4,000 will go into this job. A municipality in Louisiana ordered "white-way" equipment amounting to $4,000, while towns in Alabama and Georgia ordered similar equipment amounting to $3,500 and $2,000, respectively. Two $3,000 "white-way" orders from Georgia towns are in immediate prospect. Jobbers report good business, particularly in supply lines. Construction projects are as follows:

Swift & Company, Chicago, plan a vegetable oil refinery at Jacksonville, Fla., to cost $200,000. Miami, Fla., plans a municipal airport to cost $1,000,000. The C. J. Patterson Corporation, Kansas City, Mo., will build a baking plant at Atlanta, Ga., to cost $100,000. The Georgia Power Company, Atlanta, Ga., has acquired municipal power plant at Winder, Ga. Paducah, Ky., plans the installation of a municipal power plant and has authorized surveys.

The Mississippi Power Company, Gulfport, Miss., plans a transmission line from Richton to McLain and vicinity, 20 miles, and from Richton to Hattiesburg, 25 miles, and will install substation equipment. The Southern Public Utilities Company, Charlotte, N. C., is negotiating for the purchase of the municipal power plant at Huntersville, N. C. The Carolina Cement Company, New Bern, N. C., plans a power plant of 5,000-kva. capacity in connection with a proposed cement mill. Miami Beach, Fla., will receive bids until June 6 for an ornamental lighting system.

## *New England Sales Volume Expands*

Not only is the current trend of sales steady in New England but the outlook for increasing business during the next month is encouraging. Orders for small motors are normal. A number of sales for 50-hp. motors are of interest. Pole line material, wire and cable are in good demand. Several service extensions provide interesting prospects for transmission line equipment. Heavy industrial equipment business is quiet, but a number of orders are pending, one of which includes a complete motor-generator set. Sales of power equipment for freezers, ice crushers and ice-making machinery are active. A prominent preparatory school in Massachusetts is planning to install equipment whose consumption will be 100,000 kw.-hr. annually. Equipment for fish freezers was recently placed in Gloucester, Mass. Construction projects are as follows:

The Twin Gas & Electric Company plans to build 6 miles of 66,000-volt transmission line in Pownal, Vt., at a cost of $30,000. The Bangor Hydro-Electric Company, Maine, will expend $50,000 for service extension. This company will make additions to the Ellsworth plant, including several 1,000 kva. transformers, rebuilding transmission lines in Washington county and on Mount Desert island. The town of Hudson, Mass., will erect a municipal power plant and has purchased three Diesel engines costing $162,000, but has not yet ordered the generating equipment.

## *Industrial Account Active in Eastern District*

Expanding industrial business is reported in the Eastern district. Several extensive projects are soon to mature, while present commitments have reached sizable levels. A cement company is completing plans for a mill in Cuyahoga County, Ohio, to cost more than $1,000,000, while a similar project will soon mature in Illinois. An automobile assembling plant will be built in Missouri to cost upward of $1,500,000, while an aircraft plant is contemplated in an Ohio city to cost approximately $1,200,000. A sulphur company operating in Texas has placed an order for two 750-kw. turbo-generating units. An iron and steel mill in the vicinity of Trenton, N. J., is contracting for motors, control equipment and other apparatus for a new addition.

A manufacturer of soap will ask bids in about four weeks for considerable equipment for a factory at Baltimore to cost upward of $3,000,000. Fractional-horsepower motor business continues satisfactory, with a fair volume of inquiries. Substation apparatus, including switchboard panels and instruments, is being purchased by new office buildings in the metropolitan district; a recent order for this account totaled about $16,000.

Central-station purchases are being limited to immediate requirements and the bulk of transactions is centered in substation apparatus. A manufacturer of transformers states that current trade is satisfactory and that the heaviest commitments are being secured from light and power companies in the metropolitan district, with inquiries exceptionally good at the moment. A producer of wire and cable reports equally encouraging accounts from metropolitan utilities, covering both substation and transmission line operations.

Transactions in the electrical appliance field show little change and continue on a reduced scale. Vacuum cleaner business has fallen off a little, but electric refrigerator account looms as an important feature of spring sales. Electric supplies for domestic service and insulating products are recording a fair volume of business. Immediate construction activities in the Eastern district include the following:

The New York Central Railroad Company, New York, will receive bids June 1 for a 2,000-kw. rotary converter and a 2,100-kva. transformer, for substation service. The New York Power & Light Corporation, Albany, N. Y., has secured permission to make extensions in transmission lines to Wells, Hope, Benson and vicinity. The Cheektowaga Crushed Stone Corporation, Cheektowaga, N. Y., plans a plant to cost $100,000. The Transogram Company, New York, will build a toy-manufacturing plant at Haskell, N. J., to cost $100,000. The Niagara, Lockport & Ontario Power Company, Batavia, N. Y., has plans for a storage plant at Angola, N. Y., to cost $45,000.

The Western Electric Company plans an addition to its plant at Kearny, N. J., to cost $1,250,000. The Philadelphia Electric Company, Philadelphia, has secured permission to install steel towers for a line in the vicinity of Fox and Westmoreland Streets. The Overbrook Hosiery Mills, Reading, Pa., plans an addition to cost $180,000. The Danville Structural Steel Company, Danville, Pa., will build two additions to cost $300,000. Baltimore, Md., plans an ornamental lighting system. The Consolidated Gas, Electric Light & Power Company, Baltimore, plan extensions in recently acquired property at Havre de Grace, Md. The General Purchasing Officer, Panama Canal, Washington, D. C., will receive bids until June 7 for electrical supplies (Panama Schedule 1878).

### *Sales in St. Louis District Show Slight Improvement*

A slight improvement is noted in the St. Louis district. Manufacturers of appliances say that the demand is holding up above that of last year, especially for ranges and other cooking appliances. Stock sizes of motors are in better demand and orders are coming in steadily. An order for substation equipment for south Missouri was placed at a cost of $3,600 and a lot of motors from 5 hp. to 25 hp. amounting to $1,800. Construction projects are as follows:

The Arkansas Power & Light Company, Little Rock, Ark., plans transmission lines at Melbourne, Ark., and vicinity. The Atchison, Topeka & Santa Fe Railway plans a power house at shops at Emporia, Kan., to cost $85,000. Chalona Brothers Packing Company, Buras, La., plans a power plant in connection with its packing house to cost complete $50,000. The Empire District Electric Company, Joplin, Mo., has applied for a permit to construct a hydro-electric plant on the White River. The Inland Utilities Company, Kansas City, Mo., has acquired the municipal power plant at Hooker, Okla. The Harrison-Smith Company, Oklahoma City, Okla., manufacturer of automobile accessories, will build a plant to cost $90,000.

The United States Zinc Company, New York, plans a mill at Amarillo, Tex., to cost $100,000. The Beaumont Import & Export Company, Beaumont, Tex., plans a lumber mill, to cost $100,000. The Valley Bonded Warehouse Company, Brownsville, Tex., plans a cold storage plant to cost $200,000. Denton, Tex., plans a municipal power plant to cost $38,000. The Burford Oil Company, Shreveport, La., plans an oil refining plant at Pecos City, Tex., to cost $600,000. Stamford, Tex., plans extensions in its municipal power plant.

### *Better Business Outlook Noted in Middle West*

While no unusual activity of business is apparent in the Middle West it is generally admitted that business is better, although not up to expectations at the beginning of the year. The automotive, steel and railroad industries are prospering and better business is in view. Maintenance purchasing is quite heavy. Purchases of one utility company average $92,000 a day. Interesting orders include: Complete condensing equipment for use with a 55,000-kw. turbo-generator, soot blowers for six boilers, economizers and air heaters, six forced-draft fans, 500,000 lb. weatherproof wire and cable and 50,000 lb. of busbar copper. There has been a good demand for pole line hardware, one manufacturer reporting last month's sales as the largest in his history. Construction projects are as follows:

The Chicago Rivet & Specialty Company, Chicago, plans a plant to cost $85,000. The Robert O. Law Company, Chicago, will soon take bids for a printing plant to cost $350,000. The Sears Paper Box Company, Danville, Ill., plans a factory to cost $100,000. The Marquette Cement Manufacturing Company, Chicago, plans a mill at Oglesby, Ill., to cost $1,000,000. The Columbia Mills, Inc., West Pullman, Ill., plans addition to textile mill to cost $100,000. The Cleveland, Cincinnati, Chicago & St. Louis Railroad, Cincinnati, Ohio, plans an engine house and shops at Beech Grove, Ind., to cost $200,000. Edinburg, Ind., will receive bids until June 4 for a municipal power plant.

Deer & Company, Moline, Ill., plans an agricultural machinery plant at Waterloo, Iowa, to cost $200,000. Parke, Davis & Company, Detroit, plans additions to drug and chemical works, to cost $2,000,000. The Chevrolet Motor Company, Flint, Mich., plans a group of five plant units at Saginaw, Mich., to cost $10,000,000. The Consumers Power Company, Jackson, Mich., plans a power plant at Grand Rapids, Mich., to cost $500,000. The Dominion Electric Company, Minneapolis, Minn., plans a factory to cost $100,000. The Dayton Power & Light Company, Dayton, Ohio, will soon begin construction of an auxiliary power plant to cost $300,000.

The Ohio Public Service Company, Cleveland, will build an addition to its Edgewater generating plant at Loraine, Ohio, to cost $450,000. The Libbey-Owens Sheet Glass Company, Toledo, Ohio, plans an addition to its plant to cost $750,000. Blair, Wis., plans a municipal power plant. Mankato, Minn., plans extensions in its municipal lighting system. Champaign, Ill., Cedar Rapids, Iowa, and Madison, Wis., plan ornamental lighting systems.

### *Much Construction Planned on Pacific Coast*

Buying is comparatively slow on the Pacific Coast, although projected construction is excellent. Power company purchases have included two carloads of pole line hardware, an indicating voltage regulator for the Bay district, at an installation cost of $12,500, and about 400 assorted small transformers for the week's aggregate business. Arizona construction prospects are very good. Bonds amounting to $4,000,000 were voted for the irrigation and electrification of the Salt River area.

Government construction includes a submarine overhauling plant and battery storage building for Marine Island and the alteration and redistribution of electric and telephone systems in the marine barracks at San Diego. Dealers' business has been only fair. Contracting business has been good, particularly in conduit and boxes.

Immediate construction of the second unit of a Kraft paper plant in Port Townsend, Wash., costing $3,000,000, has been announced by the National Paper Products Company, a Zellerbach subsidiary, and the purchase of two 3,500-hp. turbines was reported. About 100 motors were reported sold by Seattle jobbers. A turbine and fire control equipment was sold to a Grays Harbor mill at a cost of $5,000. Contracts let include approximately $18,000 worth of weatherproof wire by the city of Seattle and an $18,000 street lighting system in Bremerton.

The city of Tacoma is planning a 50,000-volt transmission line between Lake Cushman and the Nisqually substation and extension of distribution lines at an estimated cost of $63,000. Industrial construction announced includes a 250,000-ft. daily capacity sawmill at Klamath Falls, Ore., with a 6,000-hp. power plant by the Weyerhaeuser Timber Company, and a 100,000-ft. daily capacity electrified mill in Centralia by the Centralia Lumber & Manufacturing Company. Construction projects are as follows:

The Los Angeles Gas & Electric Corporation, Los Angeles, plans a storage plant at Alhambra, to cost $55,000. The H. C. Smith Company, Los Angeles, manufacturer of oil well equipment, plans a new plant to cost $100,000. Uttley & Kleindenst, Oakland, engineers, are drawing plans for a cold storage plant to cost $400,000. Eugene, Ore., will receive bids until June 5, for the Leaburg unit of the municipal hydro-electric project, to cost $1,500,000. Ellensburg, Wash., plans addition to its municipal lighting plant. Long Beach, Santa Ana, Los Angeles, Bakersfield, Burbank and Oroville, Calif., plan installation of ornamental lighting systems. The county supervisors, Los Angeles, will receive bids until June 4 for an ornamental lighting system on Whittier Boulevard, estimated to cost $54,500.

# Activities of the Trade

## General Electric Welding Two New Factory Buildings

Two new factory buildings, all the structural work of which will be arc welded instead of riveted, are now being erected by the General Electric Company. One of these will be an addition to the General Electric plant in Bridgeport, Conn., and the other will be located at the company's Pittsfield, Mass., plant. These mark a second step in the General Electric program, recently announced, of utilizing welding in the construction of its new buildings.

The first General Electric welded building was erected in Philadelphia, as an addition to the switchgear manufacturing plant there. This structure, approximately 140 ft. wide, 600 ft. long and 50 ft. high, contains about 1,000 tons of welded structural work, and is chiefly notable because of the large number of welded trusses used in the roof structure, and the fact that it is the heaviest and largest steel structure thus far welded. The new building at Bridgeport is to be a small, single-story structure, 64 ft. wide and 42 ft. long. The Pittsfield building will be a two-story structure of beam and column construction, about 40 ft. wide by 280 ft. long, and containing about 250 tons of steel. It will be used in the manufacture of molded products.

---

The James R. Kearney Corporation, 4224 Clayton Avenue, St. Louis, manufacturer of overhead and underground utility equipment, announces that Joseph D. P. Hoffman has joined its engineering staff as assistant designing engineer. Mr. Hoffman was formerly with the Southwestern Bell Telephone Company as field exchange engineer.

Servel Sales, Inc., 51 East 42d Street, New York City, has concluded a contract with the Commercial Investment Trust Corporation of New York City whereby there is available for all Servel and "Electrolux" dealers a modern financing plan for both wholesale and retail refrigerator sales.

The Roller Bearing Company of America, Newark, N. J., announces that it has concluded the purchase of the plant of the Mercer Motor Car Company in Trenton, N. J. The Mercer plant occupies 11½ acres and the buildings have 175,000 sq.ft. of floor space.

Tork Clocks, Inc., 12 East 41st Street, New York, have placed on the market a line of electrically operated clocks that can be furnished for any voltage for either alternating or direct current use and which have a reserve of 24 hours to take care of possible interruptions to current. They are guaranteed for unusual timekeeping accuracy under all ordinary temperature conditions. The line includes wall clocks for stores and offices, double faced hanging clocks, and double faced street clocks. There is also a program signal wall clock which will ring a program of bells on any daily schedule desired.

The Kuhlman Electric Company, Bay City, Mich., manufacturer of power, distribution and street lighting transformers, announces the appointment of the Enterprise Electric Company, 1425 M Street, Lincoln, Neb., as its representative. The Enterprise company will carry a stock of transformers.

The Joslyn Company, Chicago, manufacturer of pole-line material and wiring equipment, has appointed J. J. Costello of 201 Devonshire Street, Boston, as its New England selling agent. Mr. Costello also represents the Electric Power Equipment Corporation and the Philadelphia Electric & Manufacturing Company, both of Philadelphia.

The Consolidated Electric Lamp Company, Danvers, Mass., has purchased the plant of the A. M. Creighton Company, Broad Street, Lynn, Mass. It is announced that the Danvers organization will start operations in Lynn about July 1 with the installation of new machinery in the new plant and the gradual abandonment of the Danvers location. The new plant has a floor space of 100,000 sq.ft.

The National Lamp Works of the General Electric Company, Nela Park, Cleveland, has developed a two-filament incandescent lamp for miners. The two filaments operate at different intensities. The major filament, giving 14 beam candlepower of light, is used until it fails. Then a simple switch, attached to the side of the lamp, is turned to throw the current into the low-candle power emergency filament.

The Benjamin Electric Manufacturing Company, 120 South Sangamon Street, Chicago, announces that Gordon E. Bloom has been appointed field sales director of its refrigerator division. Mr. Bloom was formerly with the Copeland Products Company at Chicago. The company also announces that A. W. Kakitty has joined the illuminating engineering department.

The Rome Wire Company, Rome, N. Y., a division of the General Cable Corporation, announces that L. A. Zima has joined the staff as district engineer in the New York office. Mr. Zima was formerly cable engineer with the Brooklyn Edison Company.

The Fitzgerald Manufacturing Company, Torrington, Conn., manufacturer of "Star-Rite" electrical appliances, announces that it has placed on the market the new "Star-Rite Empress" waffle iron exclusively equipped with a heat indicator. The company also has placed on the market the "Star-Rite Hand Vac," a light hand-held vacuum cleaner.

## Armstrong Company Adds Directors and Changes Name

C. C. Armstrong of the Armstrong Manufacturing Company of Huntington, W. Va., announces that the company's name has been changed to the Armstrong Electric & Manufacturing Corporation. With this change a number of new directors have been brought into active participation in the company. Mr. Armstrong states that the company will now be able to concentrate new manufacturing, financing and merchandising facilities on Armstrong products while at the same time developing new products. The first of these new products is expected to be ready for formal announcement during the summer and for delivery in the early fall. The company is now producing its table stove in bright colors in addition to white.

At the meetings of the new Armstrong board of directors there now appear the following new directors: Thomas E. Spence; William S. Yerkes, vice-president and director of the General Outdoor Advertising Company; William C. Beckers, director of the Allied Chemical & Dye Corporation; J. Roy Allen, director of the American Hide & Leather Company; C. R. Berrien, vice-president of the Central Union Trust Company, New York; Hubert K. Dalton, president of the Dalton Tool Corporation; Gardner B. Perry; Harold Will, vice-president of the Will & Baumer Candle Company, and W. R. Westerfield, director of R. F. Westerfield & Company.

Thomas E. Spence, who has been an official of a public utility company and who has more recently been associated with the Hamilton Beach Company, has been elected president of the Armstrong corporation. Mr. Armstrong will be personally in charge of research and development of new products and equipment, and in addition to the active services of the directors named above the corporation will have the close co-operation of a number of important associates, each of whom has taken a financial interest in the business.

---

Fostoria, Inc., New York City, manufacturer of lighting fixtures and electrical supplies, has leased the building at 59 West Fourteenth Street. The company has installed modern showrooms where it will display its complete line of merchandise.

The Union Electric Manufacturing Company, Milwaukee, manufacturer of control equipment, announces that it has appointed the Frederick Rall Company, Inc., 52 Warren Street, New York City, as successor to Curtis & Carhart, Inc., who retired from active business on May 1. The company also is establishing at 52 Warren Street, New York, a direct factory representative, Frank P. Caproni, who will take care of all direct factory business and service, particularly drum-type apparatus and special types of electric motor control equipment.

# Electrical Patents

*Announced by U. S. Patent Office*

(Issued May 1, 1928)

1,668,197. Suspension Tower; G. R. Falkiner-Nuttall, San Francisco, Calif. App. filed June 2, 1926.

1,668,199. Automatically - Controlled Electric Heating System; E. L. Fonseca, Newark, N. J. App. filed Jan. 19, 1927. Applicable to hair waving machines.

1,668,201. Current-Rectifying Unit and Method of Preparing the Same; E. R. Gill, Sr., Yonkers, N. Y. App. filed Sept. 25, 1926.

1,668,249. Automobile Riding Amusement Device; F. S. Rich, Los Angeles, Calif. App. filed Dec. 13, 1926.

1,668,250. Electric Laundry Iron; E. J. Rohne, Minneapolis, Minn. App. filed March 23, 1926.

1,668,251. Gas-Burner Control; E. H. Ryon, Pasadena, Calif. App. filed Oct. 29, 1924.

1,668,253. Safety Grounding Connection; R. A. Schmitt, San Diego, Calif. App. filed April 28, 1926.

1,668,272. Synchronous Motor; V. A. Flynn, St. Louis, Mo. App. filed Aug. 2, 1926. Which possesses the mechanical features of an asynchronous motor and are adapted to carry variable load at synchronous speed.

1,668,273. Synchronous Motor; V. A. Fynn, St. Louis, Mo. App. filed Aug. 11, 1926. In which a flux revolving synchronously with respect to the primary is produced at sub-synchronous speeds.

1,668,278. Reciprocating Electric Motor; J. D. Langdon, Los Angeles, Calif. App. filed Oct. 8, 1926.

1,668,285. Electric Power - Generating System; J. Pope, Brookline, Mass. App. filed Jan. 17, 1923.

1,668,293. Apparatus for Electrically Treating Liquids; F. F. Van Tuyl, Ann Arbor, Mich. App. filed Oct. 1, 1925.

1,668,310. Lightning Arrester; G. R. Folds, Evanston, Ill. App. filed May 28, 1923. For low voltage electric circuits, such as telephone, telegraph and signal systems.

1,668,343. Signal; W. Sparks, Jackson, Mich. App. filed July 16, 1920. Motor driven or other type of horn.

1,668,346. Suspension Link for Overhead Contact Wires and Method of Using Same; T. Varney, Sewickley, Pa. App. filed May 2, 1925.

1,668,365. Self - Starting Synchronous Motor; C. I. Hall, Fort Wayne, Ind. App. filed Feb. 5, 1925. Having a disk rotor.

1,668,366. Compensated Asynchronous Machine; L. Hartwagner, Dresden, Germany. App. filed Aug. 9, 1923.

1,668,377. Transformer for Electric-Arc Cutting and Welding Apparatus; F. C. Owen, Fayetteville, N. C. App. filed Nov. 12, 1925.

1,668,381. Electrical Connecter; C. A. Schild, Ft. Wayne, Ind. App. filed Oct. 30, 1923.

1,668,404. Separator and Plate Holder; F. E. Hollen, Chippewa Falls, Wis. App. filed April 30, 1926.

1,668,417. Heating Apparatus; S. M. McConnell, Tampa, Fla. App. filed April 28, 1927. With forced air draft.

1,668,434. Liquid-Testing Apparatus; E. W. Todd, Mitchell, Neb. App. filed Nov. 23, 1926. For electrically determining the hydrogen ion concentration of liquids.

1,668,450. Cut-Out; J. M. Fried, Vicksburg, Miss. App. filed Oct. 27, 1922. With means for preventing short-circuiting or overfusing.

1,668,457. Rate-of-Flow Indicator with Electric Integration for Fluids and Gases Flowing Through a Venturi Tube; W. Kath, Berlin-Friedenau, Germany. App. filed Aug. 24, 1921.

1,668,463. Trolley Head; C. Pandolfo, Montevideo, Uruguay. App. filed March 28, 1927.

1,668,477. Heating Element; H. Westergaard, Solvang, Calif. App. filed Nov. 19, 1926.

1,668,513. Protector; G. A. Millward, Brownsville, Pa. App. filed June 12, 1926. For inclosing a live electric conductor wire, for the protection of workmen.

(Issued May 8, 1928)

1,668,554. Asynchronous Polyphase Electric Motor; F. Ernstein, Roubaix, France. App. filed May 28, 1923. With means for operating it at two or more speeds.

1,668,581. Electrical Insulating Knob; D. McI. Brown, Prince Rupert, B. C., Canada. App. filed Sept. 24, 1925. For low-tension wiring.

1,668,587. Electrical Apparatus; E. Dickey, Dayton, Ohio. App. filed Dec. 18, 1922. Farm-lighting unit.

1,668,605. Trip Mechanism for Oil Burners; C. A. Reif, Buffalo, N. Y. App. filed Sept. 24, 1926.

1,668,606. Connecter Plug; T. C. Roberts, New York, N. Y. App. filed Aug. 18, 1921.

1,668,615. Device for Controlling and Adjusting the Current Passing Through an Arc Fed with Alternating Current; P. M. G. Toulon, Puteaux, France. App. filed June 29, 1926.

1,668,636. Display Sign; O. C. Duryea, Knoxville, Tenn. App. filed July 1, 1924. Designed to be illuminated intermittently by the movement of a door.

1,668,654. Direct-Current-Transforming Apparatus; C. R. Moore, Maplewood, N. J. App. filed March 23, 1927.

1,668,699. Flexible Conduit for Electric Wires; F. D. Saylor, Detroit, Mich. App. filed July 20, 1925.

1,668,707. Air-Conditioning Humidifier; C. J. Allen, Minneapolis, Minn. App. filed Jan. 23, 1924.

1,668,711. Regulation of Electric Circuits; C. T. Evans, Milwaukee, Wis. App. filed Aug. 2, 1923. Intensity control of alternating current circuits for lighting as with regulators of the variable inductance type.

1,668,731. Electromagnetically-Operated Switch; G. E. Perry, Chicago, Ill. App. filed July 12, 1920.

1,668,735. Circuit Breaker Control; W. M. Scott, Tredyffrin Township, Chester Co., Pa. App. filed May 12, 1924.

1,668,740. Battery Electrolyte Compound; L. R. Steele, Boulder, Colo. App. filed March 2, 1922. Comprising a suspension in water of a powdered compound formed from a soluble silicate and ammonium sulphate.

1,668,741. Method of Making Storage Batteries; L. R. Steele, Boulder, Colo. App. filed Feb. 28, 1923.

1,668,752. Electromagnet; A. E. Anderson, Milton, Mass. App. filed April 23, 1925.

1,668,783. Electric Welding Apparatus; W. E. Rupley, Los Angeles, Calif. App. filed April 13, 1925.

1,668,789. Lighting Fixture; W. Symmes, G. H. Harman and C. F. Duval, San Francisco, Calif. App. filed June 9, 1926.

1,668,798. Electric Meter; H. R. Bartlett and H. J. Blakeslee, West Hartford, Conn. App. filed May 26, 1927. Portable rotating standard meter with means for using as a watt meter for indicating the power or load on a circuit.

1,668,801. Storage-Battery Plate; J. H. Calbeck, Joplin, and J. A. Schaeffer, St. Louis, Mo. App. filed July 26, 1924.

1,668,828. Electrical Switch; A. G. Steinmayer, Chicago, Ill. App. filed Jan. 19, 1924.

1,668,831. Automatic Clamping Ceiling Fixture; A. K. Sutherland, Milwaukee, Wis. App. filed July 31, 1925.

1,668,847. Means Adapting Electric Flash Lights for Testing Electric Circuits; L. T. Hook, Seattle, Wash. App. filed Jan. 29, 1927.

1,668,859. Furnace-Ignition Device; D. H. McCorkle, Berkeley, Calif. App. filed June 8, 1925.

1,668,863. Electrolytic Device; W. Morrison, Chicago, Ill. App. filed Sept. 15, 1924. Rectifier type.

1,668,880. Door or Curtain Operating Mechanism; E. J. Vallen, Akron, Ohio. App. filed June 3, 1927.

# New Trade Literature

DIESEL-ELECTRIC DRIVE FOR MARINE EQUIPMENT. — The General Electric Company, Schenectady, N. Y., has issued bulletin GEA-867 describing and illustrating the Diesel-electric drive. The company also is distributing the following bulletins: GEA-447B, in which it gives illustrations and data on tugboats equipped with the Diesel-electric drive; GEA-868, covering Diesel-electric drive for ferryboats; GEA-870, covering Diesel-electric drive for passenger and cargo vessels and ships of special type; GEA-871, covering Diesel-electric drive for tankers; GEA-886, describing electric motor and control equipment for deck auxiliaries, and GEA-946, describing electric motor and control equipment for under deck auxiliaries.

ELECTRIC RAILWAY ACCESSORIES. —Supplement No. 1 to catalog No. 20 issued by the Ohio Brass Company, Mansfield, Ohio, describes its new electric railway devices such as clamps, bonds, headlights, frogs, etc., brought out since the issuing of its catalog No. 20.

LIGHTNING ARRESTERS.—"We Know —They Believe—Now They Know" is the title of booklet No. 252, the eighth of a series covering the technical features of the crystal valve lightning arrester as they apply to modern lightning protection and which is being issued by the Electric Service Supplies Company, Seventeenth and Cambria Streets, Philadelphia.

COUNTERS. — The Bristol Company, Waterbury, Conn., has issued bulletin No. 365 describing the different types of Bristol counters for use in automatic machines of all kinds as punch presses, printing presses, conveying machinery, pumps, textile machinery, etc., and wherever there are mechanical operations to be counted. It contains illustrations and also a few methods of installing the counters.

STEEL POLES.—Catalog No. 130 issued by the Truscon Steel Company, Youngstown, Ohio, describes and illustrates the Truscon copper bearing "Weltrus" steel poles. The catalog contains data and information on weight, strength, and dimensions of standard types of "Weltrus" steel poles.

CRANE.—The Whiting Corporation, Harvey, Ill., is distributing bulletin No. 185 describing its hand power crane.

AIR COMPRESSORS AND TURBINES. —The General Electric Company, Schenectady, N. Y., is distributing bulletin GEA-588A describing and illustrating its geared centrifugal air compressors. The company also has issued bulletin GEA-197A covering its type D-54 mechanical drive turbines.

FUSED SWITCHES.—A bulletin issued by the W. N. Matthews Corporation, St. Louis, covers the different types of Matthews "Fuswitches." Illustrations are given showing various installations.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered, further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number:

An agency is desired in Santiago, Chile (No. 31,220), for electrical appliances.

An agency is desired in Berlin, Germany (No. 31,244), for electric hand and face drying machines and household motor-driven appliances, and another (No. 31,243), for electric hair and hand driers.

An agency is desired in Vienna, Austria (No. 31,292), for electric heating and cooking apparatus and household electrical appliances.

An agency is desired in Munich, Germany (No. 31,241), for household electrical appliances, especially washing machines, resistance wire and electric refrigerators.

Purchase is desired in La Guayra, Venezuela (No. 31,285), of electric refrigerators.

Purchase is desired in Nuremberg, Germany (No. 31,286), of telephones.

Purchase is desired in Leipzig, Germany (No. 31,242), of electric washing machines.

An agency is desired in Leipzig, Germany (No. 31,245), for small electric washing machines.

## *How Can Utility Companies Help Stabilize State Commissions?*

GENERAL satisfaction with regulation, and more especially with the personnel of the public service commissions, is perhaps too much to expect. Yet something should be done to offset the political moves made just before state political conventions to dispense with the commissions. Until greater faith is shown in the commissions by the general public it must be expected that the commissions will have a political rather than a judicial and economic aspect. This does not augur well for stability or steadfastness of purpose, does not assure the public of righteous judgment in disputes, and means continued inroads on the time of utility executives that ought to be devoted to the business itself.

We realize, of course, that any attempt at co-operation between the utilities and the commissions would be misinterpreted to the detriment of the commissions. However, if the utilities will obviate as much as possible any cause of complaint, there would be little occasion for the public or the politician to harass the commissions. The less of law or supervision business has, the better for business and the greater its opportunity to render satisfactory service. Therefore the utilities should make regulation successful by not meriting much of it. Then the life of commissioners would be more pleasant and their relations with the public more agreeable and satisfying.

* * * *

## *An Official Viewpoint That Should Be General*

COMMENTING upon reported showings of twenty-three California cities operating municipally owned light and power systems, State Controller Riley made the following very pertinent statement: "The accounting system of municipally owned public service enterprises is of a character that prevents the controller from giving adequate information covering their operation. It is impossible to ascertain whether there is a loss or a gain, as the statements furnished are in the main 'flow of cash.' Each year shows a tendency on the part of municipalities in this direction, and the Legislature should require proper accounting methods for the protection of the taxpaying public. Governmental agencies might well set an example by the adoption of sound accounting methods and thereby definitely dispose of the controversy regarding costs that now exist as between publicly and privately owned utilities."

We have contended that all public utility service, no matter by whom rendered, should be subject to regulation as to rates and quality of service. In some states, notably Wisconsin, such regulation obtains; but in most of the states the municipalities have been successful in their efforts to keep their affairs free from state scrutiny. That is the reason so little is known of municipal operations and why so much that may not be so is spread broadcast by municipal ownership zealots. When more state officials and legislatures show a disposition to ferret out the truth, as has the State Controller of California, for example, the real facts on municipal ownership will become known.

## *Cheer from Battle Creek*

AMONG the very many men who see a brilliant future for the electrical industry, none is more optimistic and none more qualified to speak from experience than Henry L. Doherty. At a time when men are asking, "What of the future? Who will carry on when the pioneers drop out?" there comes a refreshing and inspiring message from Battle Creek. There, watching as it were from the side lines while gradually recovering from a rheumatic ailment, Mr. Doherty sees "nothing but expansion and still further expansion ahead."

Mr. Doherty's message to the ELECTRICAL WORLD, printed in our news columns this week, reflects the sane optimism and the well-based confidence of a man who has lived with and for the industry through the generation in which it has made industrial history. Through his prophecy sounds, not the note of doubt that could easily be pardoned to a leader temporarily inactive because of ill health, but a ringing challenge to all doubters from a leader longing to be back on the field. When he feels this way, it is no wonder that other leaders in full strength and vigor echo his enthusiasm.

* * * *

## *Congress Investigates Superpower Finance*

INVESTIGATORS will find that some one has made money out of central-station tie-ups. By far the most guilty culprit will be found to be the American power consumer, who is getting electrical energy at steadily decreasing cost. Intelligent elimination of waste and unnecessary human labor always produces large profits. In the case of electric power, enormous savings have been made by group operation of properties and the installation of the most efficient generating equipment. Wealth has been created by conservation rather than by extortion.

If a few hundred men of courage and energy have made fortunes for themselves by making these savings for the consumer of electricity, it will not be held against them. The fortunes are more respectable than many which were founded before the day of the great central-station companies. It is not a crime in the United States of America to get rich selling people what they need at rapidly decreasing prices.

## *Low-Voltage Neon Tubes*

DEVELOPMENT of the hot cathode has made possible the use of low-voltage neon tubes. One of these tubes, recently described by C. G. Found and J. D. Forney before the American Institute of Electrical Engineers, gives an output of 10,000 lumens. This tube was rated at 220 volts and was 2.2 cm. in diameter and 125 cm. long. Measurements of the over-all efficiency of direct-current tubes give 12 to 15 lumens per watt and of alternating-current tubes give 10 to 12 lumens per watt. These efficiencies compare favorably with those of 100-watt tungsten-filament lamps.

Further developments in glow-discharge lamps may be expected now that the cathode drop has been reduced. Investigations of color emanations from various gases and of better methods for starting tubes offer attractive possibilities. The voltage necessary to ionize a gas is never greater than 25, and from the point of view both of efficiency and of luminosity prospects are good for a great commercial development in glow lighting.

* * * *

## *Aspects of the Problem of Radio Interference*

PUBLIC relations and residential service expansion are closely associated with the use of radio in the home. This justifies individual and concerted attack by power companies upon the problem of radio interference. The outlook for further progress is encouraging, and the technique of suppression has advanced to the point where perhaps 50 per cent of the legitimate complaints can be met without the drastic step of replacing the apparatus unit (be it wire or device) diagnosed by the skilled maintainer as the seat of trouble. The manufacturer of radio sets and accessories is likely to come into the picture as a more active influence toward the improvement of reception conditions, and recent advances in the design of insulators, power noise traps and voltage regulators look very promising.

The precision of voltage control feasible at the household outlet in central-station service without the investment of considerable totals in newly designed devices is far below the requirements of some of the latest alternating-current tube sets. It has been suggested that the incorporation of such devices into the assemblies of high-grade receiving sets may well be considered by the radio manufacturer as a betterment, the cost of which should be absorbed by the selling price without adding unduly to the purchaser's outlay. The manufacturers of heavy-duty electrical equipment for home service, like automatic-control push-button elevators and grouped refrigerators for apartment-house use, are also confronted by the possibility of being asked to provide in their future designs for the inclusion of suppressive devices by whose use the high-grade sets within reach of occupants of such buildings can in many cases be made to render far better service, especially in installations operated by direct-current motors.

In the long run, there is no need to say, the consumer of high-grade service must pay its cost, and if purchasers of space radio sets continue to demand extreme sensitivity in distance reception and minimum interference from local or territorial disturbances, the industry will have to co-operate still more effectively in working toward these objectives. Progress in the elimination of line disturbances has now attained a high degree of success, and the power companies are liberally meeting this cost. The allocation of the cost of preventive measures internal to household service devices remains to be considered and applied along the lines of a standard industry procedure, so to speak. The spread of radio network broadcasting and outlook for wired-wireless service over local distribution systems bid fair to contribute toward the solution of many problems in interference through a growing popular appreciation of the superior quality of reception attainable in this way.

* * * *

## *Census Data Needed*

THE electrical industry, like any other element of American business, believes in statistics and has come to rely upon the government's census data as authoritative. Census figures on operations of the electrical industry constitute an essential part of that pool of information to which not only all Americans but indeed all civilized men in whatever country contribute and on which they are in turn able to draw. We all profit from it—directly in business, indirectly in the general advancement that flows from a greater fund of facts.

In the light of these things it comes as a surprise to learn that only 50 per cent of the returns have thus far been received by the Bureau of the Census for the electric light and power census of 1927 as against nearly 75 per cent for the biennial census of manufacturers, though both canvasses began in January.

True, the electrical schedule is complex; to fill it out entails a great deal of work especially on the part of companies responsible for returns on many individual properties. But there is a strong probability that the laggards are not those on whom the heaviest burden falls. The bureau cannot proceed with its tabulation until all returns are in. Every delay in reporting delays the publication of the result. It is not good business to wait until 1929 for 1927 statistics, and it is to be hoped that responses will be made promptly to the Census Bureau.

* * * *

## *Does the Contractor Need Relief or Reform?*

IN A WAY the electrical contractor seems to be in about the same position today as the American farmer. He is demanding relief, but what he really needs is reform. Business has been bad with him. He has been working hard and doing good work, but he has not made money. He is economically sick. That makes him unhappy, which naturally warps his judgment. He is sorry for himself. He maintains that something should be done about it, but he does not recognize and assume his inescapable responsibility to do this "something" for himself.

In vetoing the McNary-Haugen bill President Coolidge pointed out in vigorous terms that what the farmer needs is not the crutch of subsidy and price fixing but the courage to face the economic facts of his business and reform his methods of marketing. The same answer could well be recast for the contractor. It is his own business methods that have led him into grief. The power company or the jobber or the manufacturer may be able to improve some of the conditions that embarrass him, but nothing that they can do will correct his own bad practices. This he must accomplish for himself.

The contractor is extremely important to the electrical industry right now, for the vital need is for more adequate wiring installations to provide for more complete equipment in home, store, office and factory. But there are too many contractors and they are fighting for business by destructive price competition. To get the price low they keep the job small, and this restricts the whole market for electrical energy and products. They do this not because they want to, but because the large number of wiremen working "on their own" with no thought of overhead has forced the business to a condition of "squeeze-price" paralysis.

In considering what should be done two points stand out. First, the American people are willing to pay a fair price for wiring. Whatever adequate wiring is worth it will bring. It need not be given away; it needs to be sold. Second, the contractor himself must put his trade in order and lift it to a prosperous economic plane. The chief trouble with the contractor is that he provides himself with no margin to cover development and sales expense. Sooner or later he must face that natural necessity. He must add something, say, to the labor charge on every job to provide funds with which to build up a public appreciation of the importance and value of adequate wiring and to establish his own reputation for work of high quality. In this way the contractors of the community might well set up in the league a co-operative fund for use in raising the local standards of the wiring business. It is futile to hope that such a situation will right itself. The contractor will have to reform his own business.

* * * *

## *Free Speech and the Point of View*

FREE speech is a text in the gospel of democracy, but the interpretation of this text depends upon the point of view. It seems to have become a special privilege for a few favored idealistic college professors, radical literary writers, yellow newspaper editors, day-dreaming pacifists, fanatical reformers and country-saving politicians. The free-speech privilege claimed by all these cults imparts a note of humor to an otherwise drab existence and introduces just sufficient vitriol to burnish the products of those who are carrying on constructive activities.

Free speech should also be granted to American business. Yet some recent happenings in this country and especially the utility investigation in Washington introduce the doctrine that business must remain mute at all times; that it must make no effort to protect the interests of its security holders or of the customers that rely upon its service even when attacks are made upon it. Priately owned and operated business should not be muzzled. It should be able to address, educate or persuade the public, and it should be wise enough to do this by using facts. Alleged exposures of bad practices and improper activities by corporation lobbies and publicity agents should not be made the reason for a doctrine that denies free speech to business. Yet this is what many politicians, editors and publicists seem to desire, according to comments and actions in recent days. The free-speech cult can send out pamphlets, maintain lobbies, write editorials and publish distorted statements with immunity, but the business it attacks must be silent.

The great national game of a certain group of citizens is to investigate private business. The specialists in free speech refuse to investigate or attack any anti-capitalistic, labor, social, municipal or governmental business enterprise, but hover like vultures above private corporations only. Unless business can and does speak, there is evidence that a revival of professional muckraking will occur, for already war has been declared against publicity about business, against economic education, against addresses by business men and against every legitimate tool of free speech that does not conform to opinions of the self-constituted "free-speech" cult which dwells as a parasite on the makers of national prosperity. Business should use its privilege of free speech now, because the "tearers down" believe their day has dawned again.

* * * *

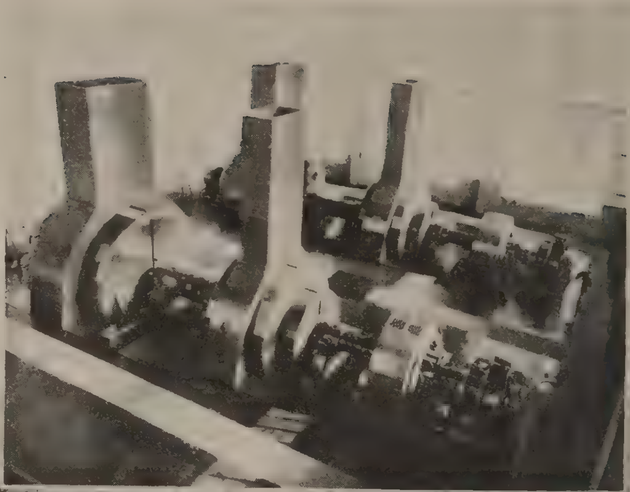
## *Technique of Interconnection Is Improving*

GRATIFYING gains in the handling of interconnected systems are apparent to those privileged to go behind the scenes at important operating centers and to hear engineers and load dispatchers discuss their problems without thought of publication. Great improvement has lately been attained in the maintenance of first-class frequency regulation on systems made up of hydro and steam plants serving extensive regions often involving several states. Load control is also making better headway, although the problem of forecasting the effect of load transfers between neighboring companies has not as yet been reduced to a simple one in relation to either local or distant networks of plants and transmission lines. Perhaps it would be fair to put it down that the more carefully operated interconnections are constantly attaining and holding to standards of service above the requirements of their customers and that many such systems are, for the time being at least, more concerned with the economic aspects of load transfer than with the solution of the frequency problem *per se*.

Experience shows that in a typical interconnection including generating plants of 1,500,000 kilowatts rating and embracing several thousand miles of transmission lines it is now possible to keep the frequency of the whole region within one-twentieth of a cycle at all times when the conditions warrant. This can be done by either hand or automatic regulation. It is at times necessary to disturb the scheduled distribution of load. Excellent automatic regulation is apparently to be counted upon in this system, even though the regulating hydro station represents only a small percentage of the combined plant kilowatts. The close regulation attained is extremely desirable for the proper distribution of loads over the various ties and, of course, to keep down large undesirable transfers between companies. With systems spread out over territories of increasing size and with so many independent companies interconnected as is often the case, more or less reaction is bound to occur at different points when trouble arises in any section. It appears on some system log sheets that thus far the transfer of load from steam to hydro plants in cases of outages on particular sections has caused the most widespread tripping of circuit breakers, but that automatic regulation indicates possibilities of improvement along the line indicated.

Plenty of troubles can be unearthed at the price of a little skillful digging, and some engineers are lukewarm advocates of tie-in operation except in emergencies; but the amount of engineering thought now being devoted to realizing the economic potentialities of interconnection justifies a liberal degree of optimism.

# *Purchased Power Serves Railroad Trunk Line*



APPROXIMATELY one-third of the 200,000,000 kw.-hr. annually required for operation on the New York, New Haven & Hartford electric trains is purchased from central-station companies. This energy is supplied at several points in addition to those receiving power from the road's own station at Cos Cob, Conn. One of the latest "points of contact" between the railroad and venders of power is the 10,000-kw. variable-ratio frequency-changer installation at Devon, Conn.

Top—Variable-ratio frequency changers at Devon, Conn.

Center—Various types of N.Y., N.H.&H. electric motive power on exhibition.

Bottom — Boston-Washington "Colonial Express" on Hell Gate Bridge.

# Selling Power to Railroads

### Liberal treatment of demand conditions essential. Examples of recent contracts for supplying heavy service to trunk lines, including the Wilmington division of the Pennsylvania Railroad

THE stage is set for negotiations of far-reaching importance between power companies and railroads in connection with the supply of energy to electrified sections of lines hitherto served by steam locomotives. Transportation men are asking the power companies to "meet them half way" in regard to terms of contracts covering this class of service, and while the advance of railroad electrification is gradual, for reasons beyond the control of its most active advocates, the railroads are looking more favorably upon the policy of buying power than ever before. At the recent regional convention of the A.I.E.E. in New Haven a session devoted to electrification problems emphasized various aspects of selling power to railroads which should not be overlooked by executives and commercial departments of power companies in territories where this class of business is either being handled today or is in prospect for the near future.

## ILLINOIS CENTRAL PRACTICE

In a paper on "The Chicago Terminal Electrification of the Illinois Central Railroad" R. F. Schuchardt, electrical engineer of the Commonwealth Edison Company, and W. M. Vandersluis, electrical engineer of the railroad, pointed out that the power contract* which was entered into in 1924 and under which operations began in May, 1926, calls for the delivery of energy from the substations of the power company at 1,500 volts direct current for traction and 2,300 volts alternating current for signaling. Three-phase energy at 4,000 volts is also provided for light and power service in the stations and shops. The charges for electricity follow the proved Hopkinson method with a "primary" in recognition of the power company's investment and a step rate "secondary" to cover the operating and service costs. To take account of variations in coal cost there is a provision for a change in secondary charges if the cost and heat content of the coal used fall outside certain limits.

The primary charge is based on the maximum amount of energy drawn under normal operating conditions. In order that the railroad company may have the advantage of the power company's large reservoir of energy and without the payment of the regular primary charge for additions required in emergencies only, abnormal demands due to such emergencies are excluded in determining the maximum demand for billing. The recognized emergencies are: (1) Abnormally heavy traffic resulting from failure of other transportation lines, unless continuing for more than ten consecutive days; (2) traffic arising from extraordinary assemblages, such as fairs, race meets, ball games, conventions, etc., unless continuing for more than ten consecutive days; (3) congestion of traffic arising from a railroad accident, derangement of power supply or other emergency conditions; (4) other excessive traffic beyond that usually carried and caused by some unusual circumstance or condition; (5) hours during which the temperature is plus 5 deg. F. or lower (the suburban cars are all electrically heated).

The limit to which electricity may be drawn under these emergencies is the capacity of the power company's equipment which may be usable for railroad service during such emergencies. This is one of the features of the contract which makes central-station service of so much greater advantage to the railroad than would be that from its own separate plant, the authors state. To insure a reasonable, continuing return on the investment made by the power company the railroad guarantees that the maximum demand that it will pay for in any month will be not less than 70 per cent of the highest demand established during the last preceding twelve months. A minimum monthly load factor of 30 per cent is also guaranteed.

One of the railroad's requirements which was finally accepted by the power company, but with some misgivings, relates to regulation of the feeder pressure. The high-speed suburban service with short intervals between trains requires a close adherence to running schedule, and this, in turn, was felt to demand close voltage regulation. The permitted variation is from 1,400 to 1,500 volts on the feeders at the point of delivery on the railroad right-of-way, which is practically at the substation.

Provision is included for additional capacity in new or existing substations as the increase in load requires. The power company may install additional equipment in its substations for uses other than this electrified railroad, and also use its equipment to serve other electrifications.

## PURCHASED POWER ADDS RELIABILITY

Sidney Withington, electrical engineer New York, New Haven & Hartford Railroad, declared that by purchasing a considerable portion of its power the company's service in the electrified zone between New Haven and New York has been made more reliable, and this has justified the extra expense in comparison with further enlarging the Cos Cob plant. He pointed out that as a rule a railroad can purchase coal on more favorable terms than power companies and that it can hire capital at lower rates. Transportation companies, he said, should not be penalized in power contracts because of emergency conditions beyond their control. G. I. Wright, engineer of electric traction Reading Railroad, stated that the power companies hardly realize what the railroads are facing in trying to handle suburban service economically and maintained that the load-factor problem and the possibilities of off-peak business should be considered.

Henry Craig Sutton, electrical engineer United Gas Improvement Company, Philadelphia, pointed out that trunk line electrification improves load-factor conditions on the power system, as the peak load of the railroad traffic may easily occur in the middle of the night. The isolated generating plant of the railroad rapidly grows out of date, whereas the modern power system keeps its generating facilities in line with the latest progress, expanding plants and bringing down the cost of power by continually making new and better installations.

---

*For details see ELECTRICAL WORLD, Jan. 10, 1925.

E. R. Hill of Gibbs & Hill, consulting engineers, New York, said that probably the most unusual feature of the Illinois Central power contract is the supply by the power company of converted current at the seven substations located along the railroad. It is most usual for the power company to supply alternating current at a single point and for the railroad to transmit and convert or transform this power itself. "The Schuchardt-Vandersluis paper," said Mr. Hill, "calls attention to a practice which has now become quite general and which is required as absolutely necessary in railroad electrification work, i.e., for the power company to supply excess demand in railroad emergencies without affecting the demand charge. In other words, the demand charge is determined by the railroad's power requirements under normal conditions and emergency drafts of power do not affect the demand billing. This is very important and really essential in railroad operation because of the fact that abnormal and emergency conditions occur much more frequently in railroad operation than in probably any other industry, and it is impossible for the railroad to control or prevent the occurrence of such exceptional demands.

### Most Recent Electrification Contract

"The most recent large power contract for railroad electrification that I have knowledge of was negotiated and consummated last year between the Pennsylvania Railroad and the Philadelphia Electric Company at Philadelphia. This is a continuation of an earlier contract covering the supply for the Pennsylvania Railroad's suburban service in Philadelphia, intended to provide for all traction requirements in that territory, including through electrification connecting New York, Washington and elsewhere if and when carried out, for a period of twenty years.

"The power company contracts to supply the power at 25 cycles, single phase, 13.2 kv. at certain main supply points in the vicinity of Philadelphia or elsewhere as may be arranged from time to time. The railroad steps up the voltage to 132 kv. and transmits at this pressure to its various transformer stations along the line.

"The outstanding feature of this power agreement is that the charges or rates are based on the actual cost to the power company of producing power in its generating stations, transmitting and converting it at the supply points. This actual cost includes fixed charges, general expenses and all other items properly entering into the total cost. In order that the railroad may be protected against any unforeseen high cost of producing power, the power company guarantees that the demand charges and the energy charge shall not exceed certain stipulated values that were estimated and set up at the time of the negotiations. Such guarantees are based on specific costs of coal and labor. Maximum rates for fixed charges are also stipulated. Some other features of the contract are: (a) Demand determined monthly based on three maximum normal clock hours per month; (b) demand may not be less than 75 per cent of any previous maximum demand; (c) guaranteed monthly load factor, 30 per cent; (d) guaranteed power factor, 55 per cent; (e) if lower rates are subsequently made to other consumers under similar conditions of supply the railroad shall be entitled to the same rates.

"At a load factor of 55.5 per cent, a coal cost of $5 per net ton, present labor rates and guaranteed maximum demand and energy costs the average cost of energy to the railroad at the supply point or points under this contract works out at 0.75 cents per kilowatt-hour."

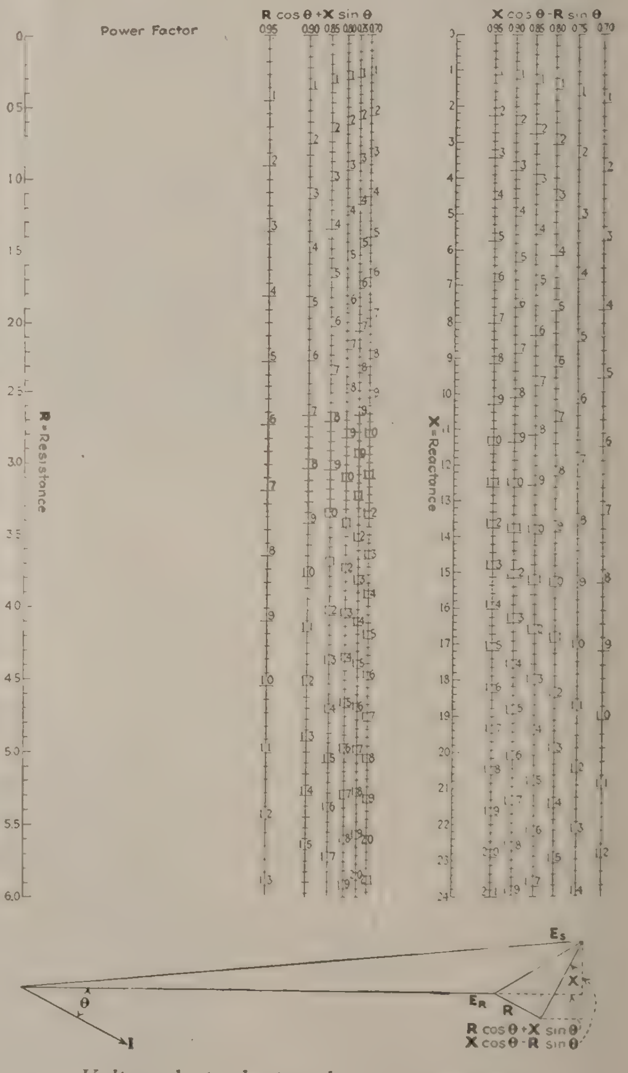
---

# Rough Check for Voltage-Drop Components

By Raymond C. R. Schulze

*Public Service Electric & Gas Company*

The accompanying chart provides a quick way to determine roughly the in-phase and quadrature components of the voltage drop along a transmission line. The chart actually gives the voltage drop per ampere for known values of resistance, inductive reactance and power factor, or $R \cos \theta + X \sin \theta$ and $X \cos \theta - R \sin \theta$. The first is, of course, the component of the



*Voltage-drop chart and vector components to which it applies* voltage drop in phase with the receiver voltage, while the second is the component of the voltage drop 90 deg. out of phase, or in quadrature, with the receiver voltage. This relationship is easily seen by referring to the vector diagram given here.

In order to obtain the total drops it is necessary to multiply the values obtained from the voltage drop chart by the number of amperes flowing in the line.

## Essential Features of Interconnection Contracts*

IT IS desirable generally to frame the rate clause so that each element is dealt with individually rather than collectively and then to simplify by the omission of such elements as are not important in the specific instance under consideration. The rate structure should be built up to contain the following elements or provisions:

1. A fixed charge for capacity reserved exclusively for the use of any one party.
2. An energy charge covering energy capacity. This may be a flat rate or a step rate, or may be modified by special rates for dump power or for off-peak power.
3. A power-factor clause.
4. Provision for emergency service.

Fundamentally, the demand billing of one system to another should be equivalent to the maximum requirements of the user minus the useful generating capacity of the latter, taking into consideration the physical condition and the degree of obsolescence of the generating equipment itself, together with the number, type and capacity of generating station tie-lines. This useful capacity is generally referred to as "relayed capacity" and consists of the total useful capacity available with the largest generating unit out of service, provided that all of the capacity has sufficient transmission line connections to render it available at all times. It is possible to simplify the demand billing by one party contracting with the other for a stipulated amount of capacity with no attention to the respective requirements of the two systems except that the generating company may require the purchasing company to hold its demand within the amount contracted for at such times as it is not expedient to allow the purchaser to exceed it. This sort of arrangement is flexible and simplifies the system operations and the billing to the greatest extent.

In the event of interconnection between two companies at several points it is helpful to system operation generally to base the demand billing upon the simultaneous demands at all metering points, using the algebraic sum and imposing few or no limitations upon the power to be taken at each metering point.

Energy should be sold at a price equivalent to average production cost within the limits of the average system load factor, plus the desired profit. It is often feasible to offer a step-rate as an inducement to the purchaser to increase his energy requirements. It may be possible to offer, advantageously, a dump-power rate for any energy used in excess of the basic block of energy contracted for. This so-called dump energy may be sold at "increment production cost plus a margin of profit" to the advantage of both parties concerned, provided it is understood that this supply of energy may be curtailed whenever the generating company deems it necessary or desirable. The modification of the energy rate may be introduced as a bonus or special rate for all energy used during specified hours of each day or specified periods of the year. The energy rate should in every instance incorporate a fuel cost.

The power-factor clause is usually incorporated in order to insure legally certain limits in the proper disposition of wattless current. Each system should take care of its own wattless current. In the event that either party to the contract consistently falls below the limit, said party is requested to improve operation or provide such equipment as is necessary to permit fulfilling the conditions.

In order to insure against impairment of the quality of service and to simplify billing, it is usual to specify that emergency service will be obtained only when requested formally, either by writing or verbally, and confirmed by writing and permission to make use of the facilities formally granted. The charge for this service should be based upon energy uses only, with no reference to the demand unless the emergency requirements should extend over a considerable period, in the event of which an agreement should be worked out between the two contracting parties to cover the specific case.

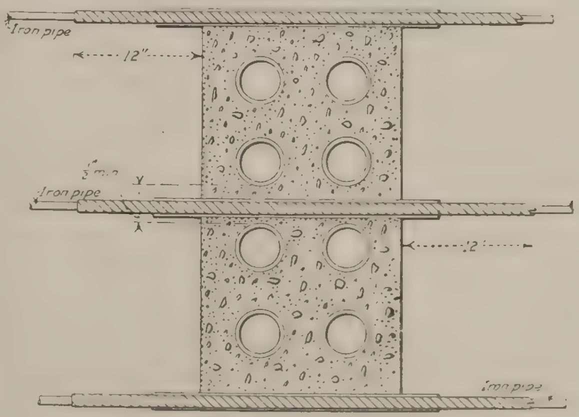
*Abstract of a report by H. E. McDowell, Texas Power & Light Company, at the eighth annual convention of the South-western Geographical Division of the National Electric Light Association.*

## Iron Pipes Through Conduit Lines

IN THE underground system of the Kansas City Power & Light Company, in which a large amount of fiber conduit laid in concrete is used, the method here illustrated for carrying iron pipes through the duct structure is used. These pipes may be gas or water services from mains paralleling the duct line. Before the concrete is poured the pipes are wrapped with one layer of paragon impregnated tape half lapped for a distance extending 12 in. on each side of the completed duct structure. Over the paragon tape are wrapped three layers of building paper so that if the pipe is later to be removed it may be pulled out of the concrete with reasonable ease. To avoid weakening the duct structure a minimum of ½ in. is set as the clearance distance between the outside of the wrapped pipe and the nearest fiber ducts in the run. The same method applies where pipes come into contact with duct lines but do not cross them.



*Method for pipe crossings of duct lines*

# Computing Compensator Settings for Automatic Voltage Regulators

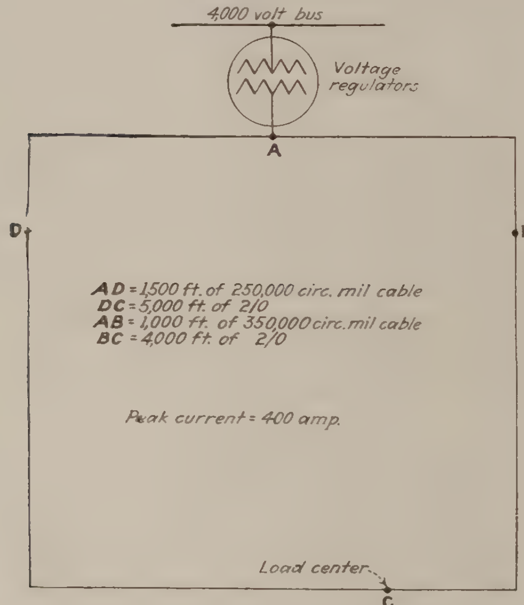
SECOND ARTICLE

By V. W. Palen

LOOP CIRCUITS.—Where there is one loop or more the first step consists in computing the resistance, reactance, and impedance values to the load center of each individual loop. For such a condition as that indicated in the accompanying figure the following procedure would obtain:

| Half of loop *ABC* | Resistance | Reactance | Impedance |
|---|---|---|---|
| (*AB*) 1,000 ft. of 350,000-circ.mil underground cable | 0.0345 | 0.0369 | 0.0508 |
| (*BC*) 4,000 ft. of 2/0 overhead wire | 0.3160 | 0.5280 | 0.6150 |
| (*ABC*) Total | 0.3505 | 0.5649 | 0.6658 |

| Half of loop *ADC* | Resistance | Reactance | Impedance |
|---|---|---|---|
| (*AD*) 1,500 ft. of 250,000-circ.mil underground cable | 0.0646 | 0.0568 | 0.0855 |
| (*DC*) 5,000 ft. of 2/0 overhead wire | 0.3950 | 0.6600 | 0.7700 |
| (*ADC*) Total | 0.4596 | 0.7168 | 0.8555 |



*Loop circuit for illustative calculation*

Combining the two halves of the loop:

$$\text{Resistance } (AC) = \frac{0.3505 \times 0.4596}{0.3505 + 0.4596} = 0.1990 \text{ ohms}$$

$$\text{Reactance } (AC) = \frac{0.5649 \times 0.7168}{0.5649 + 0.7168} = 0.310 \text{ ohms}$$

$$\text{Impedance } (AC) = \frac{0.6658 \times 0.8555}{0.6658 + 0.8555} = 0.374 \text{ ohms}$$

Since the primary current at the peak is 400 amp. and the ratio of the current transformer is usually 20 to 1:

$$\text{Resistance drop } (AC) = \frac{0.1990 \times 400}{20} = 3.98 \text{ volts}$$

$$\text{Reactance drop } (AC) = \frac{0.310 \times 400}{20} = 6.2 \text{ volts}$$

$$\text{Impedance drop } (AC) = \frac{0.374 \times 400}{20} = 7.48 \text{ volts}$$

The compensator in this case, therefore, would be set for the values $IR = 3.98$, $IX = 6.2$ and $IZ = 7.48$.

Computations for the double loop and triple loop circuits will appear in later articles.

# Operator Discusses Motor Bearing Experience

IN DISCUSSING his experience with sleeve- and ball-bearing motors in a steel fabrication plant the superintendent made the following comments to a representative of ELECTRICAL WORLD:

"It is difficult to make recommendations or draw conclusions as to the better type of bearing—each has a definite field. We have in our shop about 63 motors (exclusive of overhead cranes), of which 54 are sleeve bearing and nine are ball bearing. The nine ball-bearing motors have been in service from one to three years and have never given any trouble. They are greased with Alemite every four months.

"We have found that sleeve-bearing motors are more or less subject to bearing and armature trouble, due to the weight of the armature wearing the bearing on the bottom side, which causes a rub on the field coils and burns out the armature. Ball bearings, on the other hand, wear evenly all around and the life of the bearing is increased considerably. In making repairs to the sleeve-bearing motors there will, of course, be interruptions, but it is difficult to state just how much loss of time this has caused. Winding burnouts occur too frequently and I would hate to hazard a guess as to the power factor, but I feel that the ball-bearing motor is the more efficient."

# Single-Circuit, 19-Mile, 110-Kv. Line Cost Estimate

IN CONNECTION with the construction of a single-circuit, 110-kv. transmission line from Ayer to Tewksbury, Mass., the New England Power Company filed the accompanying cost estimate with the Massachusetts Department of Public Utilities, based on 1927 conditions. The right-of-way acquired was wide enough to permit the ultimate erection upon it of three 110-kv. or two 220-kv. circuits. The towers are spaced 6.8 per mile with 1.8 strain towers per mile. Eight- and nine-disk insulators are provided.

ESTIMATED COST OF 110-KV. LINE, SINGLE CIRCUIT
(Length, 18.96 Miles)

| | |
|---|---|
| Clearing and burning brush | $26,000 |
| Towers: | |
| Excavation | 20,500 |
| Setting footings | 13,400 |
| Distribution of steel | 7,000 |
| Erecting | 12,600 |
| Distributing miscellaneous material | 2,800 |
| Stringing power and ground wires | 14,000 |
| Towers, 50-ft. flexible steel | 49,400 |
| Power wires, one three-phase circuit, No. 4-0 copper, 13-ft. 6-in. horizontal spacing | 36,400 |
| Overhead ground wires, two ⅜-in., crucible steel | 5,300 |
| Power insulators and hardware | 13,900 |
| Tie wire, protecting and splicing sleeves | 200 |
| *Right-of-way, 250 ft. wide; 125 ft. cleared | 96,700 |
| Total | $298,200 |
| Contractor's expenses, 10 per cent | 29,820 |
| Total | $328,020 |
| Engineering expense, 5 per cent | 16,410 |
| Grand total | $344,430 |
| Per mile | $18,166 |

*Sufficiently wide for additional lines.

# Railroad Electrification

### Causes for retarded application of electricity as motive power. Factors slowly forcing use, especially in population centers. Economy of purchased power through load diversity on central stations

By N. S. HINMAN
*Commonwealth Edison Company, Chicago, Ill.*

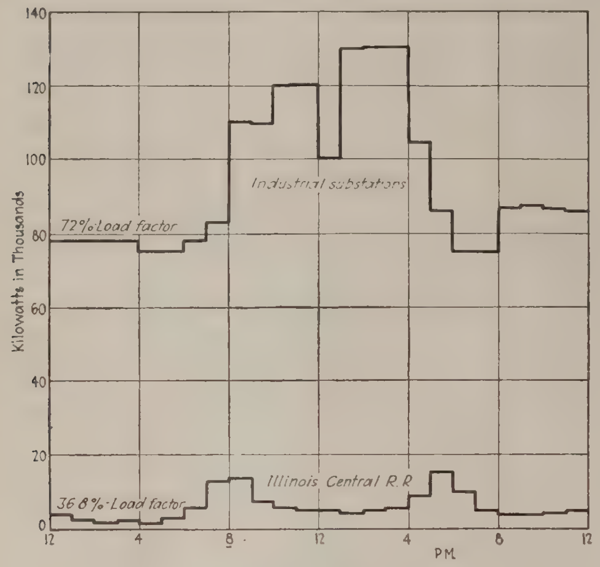
*Curve-catenary construction Philadelphia-Wilmington division. Pennsylvania Railroad*

SINCE 1895 there have been about eighty instances of steam railroad electrification in all parts of the world. The development, however, has not kept pace with the increasing volume of the transportation load and the tremendous strides made, through the invention and improvement of apparatus, in the effectiveness of electrical energy for all kinds of power use. With an ever-growing intensity of traffic, with increasing values of land at terminals, of air rights and rights-of-way in the vicinity of population centers, with city governments crying against the nuisances of smoke and noise and with the constant demand for more speed and comfort on passenger trains, the days of the steam-drive locomotive, at least near population centers, would appear to be numbered.

Increasing capacity, both track and terminal, has its main importance in large city terminals, on main line heavily traveled roadbeds, and in particular in connection with suburban service. Thus the necessity for relieving congestion led to the electrification of the Pennsylvania stations in Philadelphia and New York and the Grand Central Terminal in New York. The acceleration of train movement was greatly increased, turning movements eliminated and switching greatly reduced. As cities increase in size and population density, the districts immediately surrounding them increase in population in an augmented ratio, making the demand on suburban train movement during morning and evening rush hours extremely heavy, while simultaneously the acquiring of additions to rights-of-way becomes an extremely costly and often physically impossible solution of the problem.

The use of multiple-unit electric trains has created a flexibility of suburban operation unattainable with steam. The lengths of trains are limited only by the lengths of station platforms, while the acceleration possible with these units greatly increases the average speed throughout the run. These two factors alone may make possible an increase in handling capacity of 50 per cent. To the people of Chicago the comparison between the suburban service of the Illinois Central under the old steam operation with that under present electrification affords a striking example of the possibilities of the latter. When congested terminals and heavy suburban services provide a high load factor on track and equipment the economy of electrification, particularly when savings due to increased capacity and to air rights are considered, is very material. The outstanding present-day example of favorable utilization of air rights made available by electrification through smoke abatement is to be found in the Grand Central station in New York, where it is claimed that the revenue derived from this source is equivalent to the fixed charges on the cost of electrification. The electrification of the suburban service of the Illinois Central out of Chicago has, through the increase of passenger-carrying capacity, reduced the cost per passenger mile very materially.

The swift development of electricity and the increasing traffic problems of the railroads, both so recent and so filled with new questions of uncertain solution, are themselves reasons for the hesitation on the part of roads to electrify. The expense entailed in making a trial step in electrification is very high, and the results of an error in judgment or a new development in equipment requiring replacement might seriously affect the finances of the pioneering railroad. The development of electrical equipment for applying energy to railroading is not yet standardized except as to basic principles, and systems now in use vary greatly. Both direct and alternating current have their advocates, conversion apparatus is just emerging from the experimental stage, while voltages in use vary from 600 to 22,000. Furthermore, the future tendency as to size, weight and speed of trains is not clearly defined. This inability to forecast the future development of electrical equipment and train operation constitutes a retarding influence against electrification, as railroad officials are naturally reluctant to face possible later changes necessitated by varying future standards.

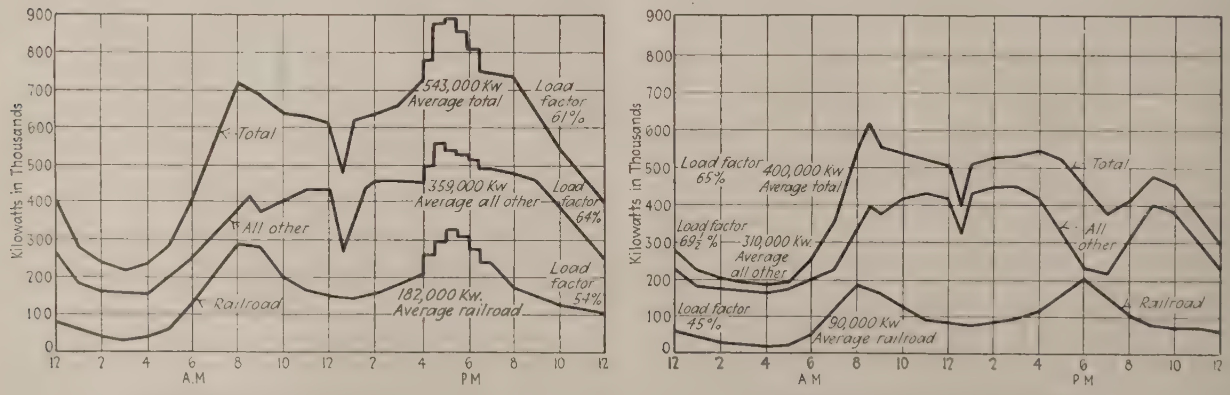


*Typical daily load curves*

Note that the "valleys" of the Illinois Central load curve coincide in general with the peaks of the industrial substation load curve, illustrating very favorably the advantages of the diversity between these two loads.

Although railroad equipment may not yet be perfectly standardized, electrical energy in ample quantity and at a low price is already available, particularly in and around large centers of population. The advantages of mass production and diversified markets permit great operating savings through fuel economies, improved efficiency of generating equipment, reduced fixed charges and, most important of all, through high load factor resulting from diversity of load. These make available near all large centers of population a motive power more advantageous in respect to both price and quality than is obtainable through the employment of steam locomotives.

A major central-station company generates such great amounts of energy that the railroad load is but a small portion of the total. Its entire staff is trained in the business of producing and marketing energy. It is possible for the central station to use more efficient, because larger, prime movers than are available to the railroad alone. Large size in units and concentration of power reduce operating costs considerably. But the strongest argument in favor of the central-station company as against the isolated plant for railroad operation is the much lower fixed charges per kilowatt-hour which result from the diversity of the central station. This generally applicable business principle of diversity is nowhere so vital as in the business of producing electrical energy because of two inherent conditions: First, the high investment required per unit of capacity, and, second, the short duration of peak loads and the ordinarily large difference between maximum demand and average demand. In the production of energy for but one class of use this latter condition is aggravated to a point where the investment layout necessary to carry the maximum constitutes a very heavy burden, since it must be carried by a much smaller average demand.



Annual peak, winter day, Dec. 15, 1926.

Average summer day, Aug. 3, 1926.

*Typical load curves of Commonwealth Edison Company illustrating advantages of diversity*

In the left-hand graph, depicting load curves on a winter day, the load factor of "all other" is 64 per cent, compared to 54 per cent for the railroad load, while in summer the load factor on the day shown for "all other" is 65 per cent and that of the railroads 45 per cent.

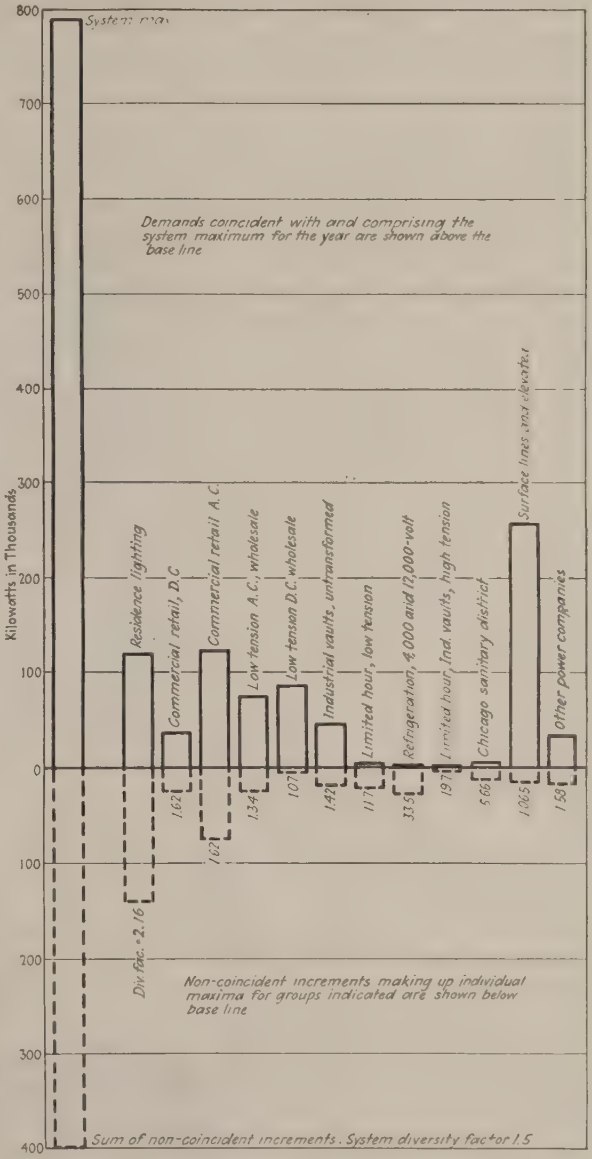
The seasonal drop in the daily average load between the winter day and the summer day is only 13 per cent for "all other," as compared to a drop of 50 per cent for the railroad load. The railroad curve represents the sum total of the surface lines, the elevated and the Illinois Central electrification.

Variation in demand is an hourly, daily and monthly variation. It is the aim of central-station companies to build up demand during off-peak periods by connecting on to the system loads whose maxima do not coincide with the system maximum. Thus, by combining the requirements of a great variety of customers, an increasing diversity of load is obtained, the use of the investment increased and the fixed charge per unit of production materially decreased. Such a procedure is impossible, or possible only within very narrow limits, when a single user or class of users are connected to the generating center. If railroad maximum demand came at the same time as the total maximum and if the load did not vary from hour to hour during the day and with the changing seasons there would be no advantage in central-station power other than the advantages of low operating costs, as distinguished from fixed charges, due to mass production. But experience indicates that the peaks of various loads do not coincide.

In general, it can be said that the morning domestic light and power load is declining, while the suburban and street railway load is increasing toward its morning peak at around 8 o'clock, as the population is carried to factory and office. Following this, the railroad load declines sharply, but the total is held up by the rise in the industrial load. In the evening the industrial load abates before the sharp evening peak on the railroad load. As this falls off the lighting load sustains that of the system. During the late evening and the early morning hours it is possible to add a special controlled load, such as ice manufacturing and other industrial uses, to build up the load factor.

The foregoing and the accompanying load curves indicate in a broad way the use of investment which can be obtained only through the connection of a varied load onto central stations. It can be readily understood that not only in technical and constructive problems, but also in the question of scientific employment of the necessary equipment through the economics of marketing, the central-station business is a very highly specialized one, requiring the utmost efforts of those engaged therein. Both the problem of obtaining energy at low operating costs through mass production and interconnection and that of increasing the use of the investment through diversity are possible only with the large diversified business of the central-station company.

In solving the many perplexing questions of railroad electrification, a mutual understanding of each other's problems by the railroads and the central-station companies is essential. Thus the nature of the railroad load curve, with its hourly and seasonal peaks and valleys, can be studied simultaneously with the load curves of other businesses supplied by the central station, with the end in view of building up load factor. In this connection the possibilities of developing the country adjacent to the rights-of-way through the availability of energy to farms and small communities are important. It is certain that to a large extent the investment in generating stations and some other equipment, especially near centers of population, has already been made and is available to the railroads. A survey of the total railroad requirements in any particular locality to learn the extent to which available generating stations can absorb the railroad load and what additional equipment may be necessary is a matter for joint action between the two industries. The question of transmission lines and equipment and distribution facilities along the rights-of-way can best be decided upon through co-operation, particularly where the distribution of energy to the adjacent countryside is a consideration. The standardization of equipment and apparatus is best approached through the combined efforts of the railroads, the electrical manufacturers and the central-station companies in order that the performance requirements desired by the roads be synchronized with the design of equipment for generation, transmission conversion and motive power.



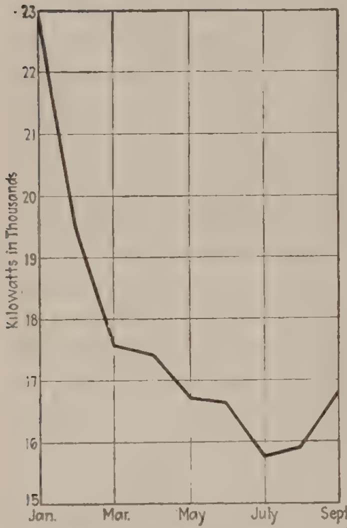
*Diversity chart—making $1 do the work of $1.50*

Showing the diversity of large groups of customers on the Commonwealth Edison Company system for 1925 and illustrating the investment saving due to this diversity of business, which at $100 per kilowatt capacity for generating equipment alone approximates $40,000,000.

No more outstanding example of the success of electrification wisely instituted through the co-operation of the railroad and the central-station company, resulting in minimized investment and power cost, can be found than in the case of the Illinois Central electrification in Chicago. During most of the year 1926 the Illinois Central operated its suburban service by steam at a loss of

$337,000. In 1927, operated exclusively by electricity, it is estimated the line will show a profit of almost half a million dollars. Simultaneously it has increased the number of trains 33 per cent, slightly reducing commuting rates, and enjoys a 20 per cent increase in patronage. Running time has been reduced from 10 to 22 per cent.

That the central-station company was able to deliver the required energy with no more than the normal increase in generating capacity is evidenced by the fact that maximum requirements of the electrification are around 23,000 kw., which come non-coincidentally with a maximum demand of the company's system of upward of 900,000 kw., while the total annual consumption of the railroad is estimated at 55,000,000-kw.-hr., as against 3,500,000,000 kw.-hr. for the whole system. From these figures it can further be ascertained that while the load factor on the entire central-station system was approximately 47 per cent, that on the 23,000-kw. maximum requirement of the railroad approximates only 27 per cent. The added utilization of required capacity as between the entire central-station system and that part necessary for the railroad alone brings out clearly the advantages of the diversity obtained through central-station generation of railroad supply power.



*Illinois Central Railroad load curves*

Average hour maxima for each month of the first nine months of 1927, illustrating month to month fluctuation of load.

The accepted basis on which the services of both the railroad and the central-station company are furnished being cost and not value, and the accepted policy of each being to sell its services at the lowest price compatible with a fair return on invested capital, their customer viewpoints coincide. Therefore, each party is seeking the same end and both can best solve their common problems through co-operation and a frank laying of cards on the table, to the end that these problems may be considered from all angles, present investment utilized to the maximum and future growth developed along sound, economic lines. This spirit of co-operation, if present in the negotiations of individual power companies and railroads, will do much toward the satisfactory solution of railroad electrification.

---

## Truck-Mounted Gin Pole Reduces Pole-Setting Costs

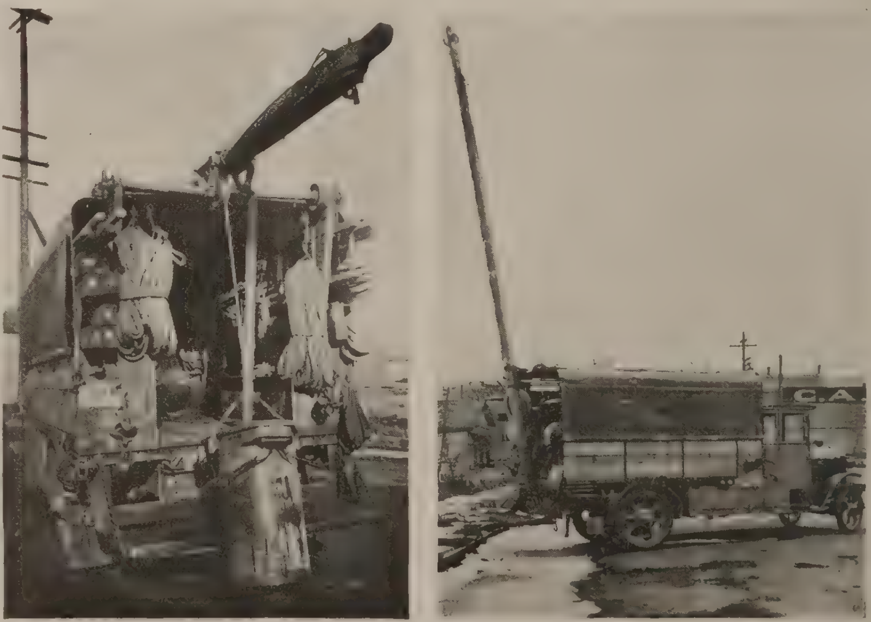
By D. A. Hord

*Superintendent of Distribution Northwestern Electric Company, Portland, Ore.*

Hand setting or similar methods of raising poles have been displaced by the Northwestern Electric Company, Portland, Ore., by a gin pole mounted on a line truck. While many utilities are now using equipment of this general character, the interesting feature of this truck is the method of mounting and supporting the gin pole and the fact that it is carried on an unusually well-equipped line truck instead of on a separate vehicle, as is so often done in similar practices.

The gin pole is shown in a lowered position for traveling and the overhead cross-shaft for hinging the pole is clearly indicated. Two lead sheaves are provided. When the one in the center is used for lifting transformers or other equipment the brace shown is used to prevent bending the shaft. Either sheave may be used for the pull line leading to a power-driven winch on the right front side of the truck. When traveling the upper end of the gin pole rests in a leather saddle at the forward end of the truck roof.

The gin pole is also illustrated in position with the four permanently connected guy cables tightened. The bottom of the gin pole fits into a socket on the rear center of the truck bed. Adjustable stiff-legs, at each rear corner of the truck chassis, are not lowered into position in the picture. The advantages of this equipment and the saving in cost of setting poles over former methods are so obvious that no comparative costs have been completed.



*Combination line truck and pole-setting rig minimizes equipment and labor costs*

# Financing Power Projects*

### Utility executive constantly faced with financial and economic questions which are just as urgent as his technical problems

By C. W. Kellogg
*President Engineers Public Service Company*

*C. W. Kellogg*

THE fact that the problems of design and construction which are involved in good engineering often require the overcoming of great physical difficulties or the exercise of a very high degree of mental training, ingenuity and courage is quite likely to lead the engineer to feel that when these difficulties have been surmounted his problem has been solved. While undoubtedly there have in the past been many cases where the skill and ingenuity of some engineer has made possible the accomplishment of some useful work which would not have been done but for the engineer, yet I believe by far the most common case nowadays is one where the engineer cannot apply his skill and knowledge until first the money to pay for the work has been raised. And raising money involves not only ascertaining by study and analysis what the economic results of a given engineering project may be, but of showing those results to the people who have spare capital in such a convincing way that they will voluntarily invest their savings therein. In other words, even after the engineer can answer affirmatively the question "Can it be done?" he must still be able to answer satisfactorily the question "Will it pay?" and this answer must be in terms that will be clear and convincing to the untechnical business man. The larger the project the longer and more difficult the solution of the economic factors tends to become.

In the case of the Conowingo hydro-electric development it is a fair statement to say that it had been a definite project for 44 years before its final realization. The economic soundness of the enterprise could not be demonstrated until high-tension transmission was developed to the point of being able to carry the large output to market without excessive loss, until the market itself had developed an absorptive capacity sufficient to utilize the output and until there existed a steam-generated system large enough to relay the hydro plant during low flow.

The great project of a deep waterway from the Great Lakes to the sea, one of the greatest of our times, depends primarily on economic considerations. No one questions the ability of engineers to construct the dams, locks and power plants necessary or incidental to this project, or to estimate with reasonable closeness what they will cost, how much power and energy they will produce, how long they will take to build, but there is a great deal of question in various people's minds about the economic effects of making the huge investment which would be necessary. This project, instead of affecting 3,000,000 people, as does Conowingo, would affect more like 50,000,000 people, and, what is more, it would not affect them all the same way, which adds another very complicated feature to the subject. To my mind the economic limits of engineering are not a narrowing force for the engineer, but just the reverse. They are a challenge to his human as contrasted with his purely intellectual faculties. They oblige him to apply his skill and knowledge for the good of the community in its broadest aspects and thus make him a more useful citizen. The age in which we live is primarily one wherein nature's forces so long unused are being harnessed for man's benefit. It is not mere chance, but a sign of the times, that the man who during the last fifteen years has done more than any other individual for the benefit of mankind is its most eminent engineer, Herbert Hoover. It is also in line with my thesis that one of his most conspicuous services during the last five years has been along the economic lines of saving waste in industry.

## Does it Pay?

Lest it might be felt from the examples I have mentioned that I have reference only to great public works in considering the economics of engineering, I have only to remind you that the principle applies even to the smallest matters and even applies in the specific questions of effecting economies. In steam power plant design, for example, we all know that it is possible to produce a kilowatt-hour from less fuel than is now being done in any existing plant, but we also know that no sensible person is going to spend the money in investment to make that further possible fuel saving unless it pays to do so.

In this matter of fuel saving the economic questions far outweigh the purely engineering ones. For example, with a low load factor and cheap fuel it might be shockingly bad economics to attempt to get even ordinary fuel economy. In northern Louisiana recently a power plant was erected at a point where approximately 300,000 B.t.u. in natural gas could be bought for one cent. Obviously any expenditure in plant investment to save fuel would be foolish, and what, in fact, was done was to utilize the cheap fuel to effect a saving in plant investment by cutting out every piece of equipment not absolutely needed. A very low investment cost per kilowatt was thus secured and still the fuel cost was less than one mill per kilowatt-hour.

---

*Read before the Boston Section, A.I.E.E.

The opposite extreme exists in one section of the country, where fuel is relatively high priced and system load requirements such that now stations can be operated at very high load factors. In such a case the relatively high investment cost necessary to secure the very latest developments for improved economy may be wisely made, not for the feat of beating a record for B.t.u. per kilowatt-hour but because, with the load factor and fuel cost obtaining, it pays to do so.

In the early days of engineering many problems of design and construction had not been solved. They were baffling and difficult, and when some of them had been solved the engineer might properly rest on his oars for a bit. Now, however, there are so many important ways in which engineering attainment has outstripped economic ability to utilize it that, whether he will or no, the engineer is forced into considering continuously the economic aspects of his business.

### Railroad Electrification

One of the great developments of the future is railroad electrification. Past engineering design and experience have absolutely answered the question "Can it be done?" It remains in each new project an economic question. In each case there is involved the great task of exposition of the advantages of electrification to officials drilled with decades of steam locomotive operation; there is also the question of railroad credit to finance these great electrification programs — the latter now happily much nearer solution than a decade ago—but both of these matters are essentially economic.

A special angle of the economic aspect of engineering is the matter of raising the money to pay for large construction projects, commonly called financing. While this is in the last analysis the problem of the investment banker, since his is the risk in buying the securities and his the responsibility in selling them to his clients, on the other hand the engineer should be familiar with the requirements of the situation, since it is one of the links in the chain connecting his conception with the actual carrying out thereof. Weakness in this link has been a frequent cause of good plans failing to come to fruition. The investment banker is used as representing the investing public, since his requirements merely represent what he knows his clients will demand before they will buy and because raising funds by direct public solicitation is usually quite impracticable.

Merely financing extensions of moderate size to an existing property need not concern the engineer. The new money is raised by a going concern either to pay for economies greater than the cost of the new money or to care for growth of business; in either case the money is raised on the company's own credit.

All financing is based on credit, and for a brand new project the establishment of the necessary credit is a matter in which the engineer plays an essential rôle. Investors are accustomed to buying securities on the basis of past earning power, based preferably on many years' record of performance; so that securities of a "construction project," not only without any earnings record but facing a year or two of construction period without any earnings, naturally meet with a good deal of what is commonly known as "sales resistance."

### Buyer's Credit May Be Used

This difficulty can be overcome by utilizing the credit of the company which is going to buy the output of the project, as was done with the credit of the Philadelphia Electric Company in the case of Conowingo, or through a contract or contracts for the purchase of the output, as was done through the Union Electric of St. Louis and other prospective customers in the Keokuk development.

Briefly, the method followed with the Conowingo project was this. The hydro companies, two in number, each owning the property respectively in Pennsylvania and in Maryland, were leased for 45 years to the Philadelphia Electric Company or subsidiaries owned by it at rentals sufficient to pay charges on the securities required to finance the project. In this way the credit of the project was as firmly established before construction began as though the water-power development were in fact one of the Philadelphia company's own power stations. In addition, the electric company definitely pledged itself to put up any money over and above that raised by the sale of securities that might be needed to finish the construction work. Through the arrangements mentioned Conowingo's credit was about as perfect as that of any privately built project could well be. A weaker credit position, paying more for the money, of course, would suffice, but in any case the credit must be there, either direct or remote, and it is impossible for the engineer to put his project through until it can be given a credit standing satisfactory to the investment banker.

This makes the establishment of earning power a problem the engineer must solve. It involves a study of markets and rates and often lengthy negotiations with consumers. The Keokuk project was authorized by act of Congress in 1905 and five years of study and negotiation for the establishment of the market for its output were required before the project could be financed. Even when the act of Congress was passed 60 years had elapsed after the original reconnaisance of Robert E. Lee, then a captain of engineers in the army, before the arrival of economic conditions made the development feasible.

Millions of horsepower in water power in this country have been surveyed, analyzed and studied by engineers and are now waiting the development of markets for their product satisfactory as to size and location before they can be developed. They are feasible as engineering projects, but the sun of economic need has not yet risen for them.

Engineering will continue for an indefinite future to concern itself with applying scientific knowledge to human use. During the last 50 years the engineering difficulties of working out these applications were so great that they required all the energies and ingenuity of the engineer. Latterly, however, I believe, as I stated at the outset, that the emphasis is shifting to the problem of applying them on sound economic lines. The effect of this latter development is greatly to broaden and to humanize engineering. No longer is the engineer merely the designer of structures and machines and the builder of great works. In future he must to an ever-increasing extent co-ordinate his expert knowledge and experience with the economic requirements of the body politic.

# Non-Supervised Substations

### Economic and public relations considerations. Steel structures for 22 kv., 33 kv. and 44 kv. used by the Alabama Power Company are simple in design and operation

By S. J. Spurgeon
*Distribution Engineer Alabama Power Company, Birmingham, Ala.*

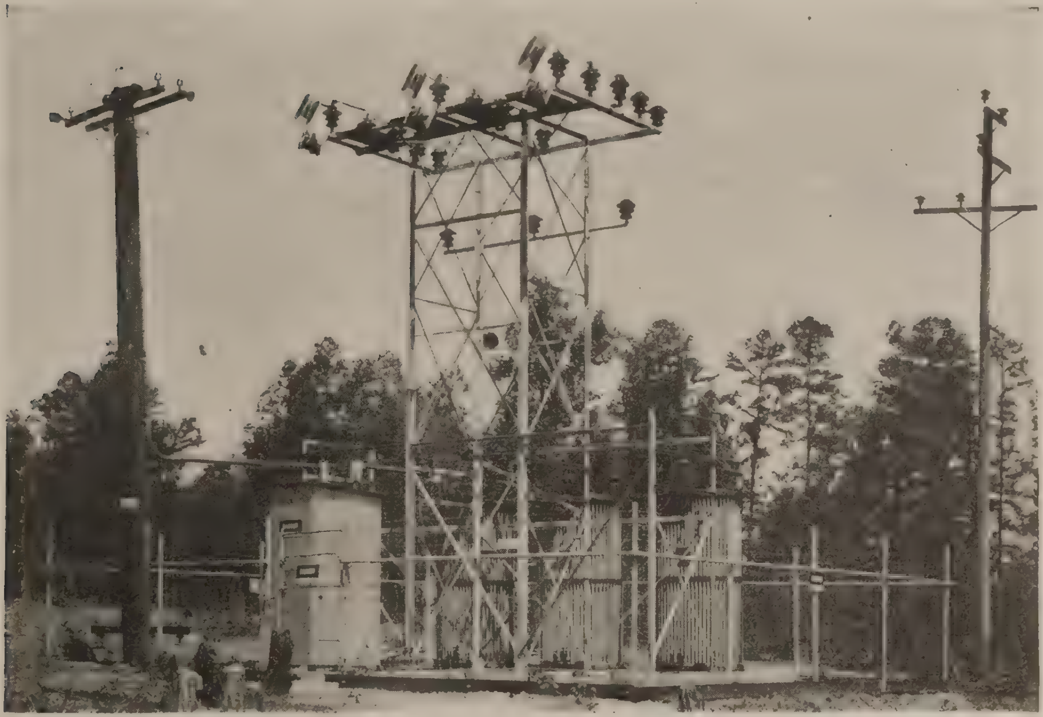


*Fig. 1—Non-supervised outdoor substation used by the Alabama Power Company*

MANY factors enter into the design of non-supervised distribution substations other than merely securing the maximum use of the equipment necessary to meet a specific set of conditions. The chief factors to consider are the policies and practices of the particular utility, the economic phases and the effect on public relations and on electrical construction carried on by the customer. Local conditions, load density, character of load and accessibility are the most important factors in determining the policies and practices of any one utility. Any one of these may be the determining factor in setting the policies and practices in connection with any individual substation. However, all of these factors must be considered jointly in order to arrive at a general policy and to determine what general practice must be followed.

The economic phase is usually the one factor that should receive the most consideration, quite often to the exclusion of all others. The initial cost must have a place in the economic phase, but against this must be balanced the cost of maintenance and operation. Different designs will necessitate different expenditures for maintenance and operation. As is well known, the cheapest design is seldom the most economical, since the difference in the cost of maintenance and operation of a cheaply built and a higher priced substation will often more than cover the overhead expense on the difference between the initial cost of the two substations. In case the added initial expenditure greatly benefits the service obtained from the higher priced substation the expenditure is justified.

Public relations can be greatly improved by careful selection of substation apparatus by appealing to community pride through the visible property. Any community appreciates the effort made by a public utility to uplift a district through pleasing construction work. The quality of service to the customers also pays good dividends in public good will. Any substation must be so constructed that service is interrupted only under extraordinary conditions and then with the least possible outage.

Consideration must also be given to the influence

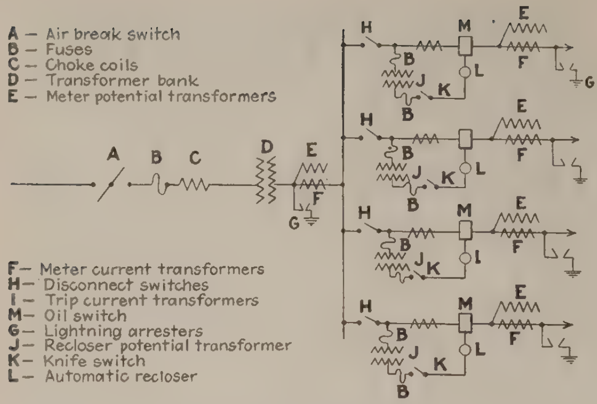

*Fig. 2—Wiring diagram of typical 44-kv. unit type step-down substation*

of the utility's construction work on similar work done within the plant of the customer. In many cases a customer will try to duplicate construction work done by the utility serving him. For the benefit of service to any customer the example set by the utility should be of the highest practical standard.

### Standard Customer Substation Used

In the development of the standard customer substation for the Alabama Power Company's system all of these points have been considered. It will be noted from the accompanying illustrations that steel has been used almost exclusively so as to obtain a permanent substation and also secure a high salvage value. These substations are very simple in design and operation. The greater number of the non-concentrated loads of this utility consist of comparatively few customers and a substation having highly flexible switching facilities is not necessary. It is, however, necessary to provide a substation that can be adapted to almost any available location. It was for loads of this class that the unit type substation treated herein was developed.

This substation is adaptable where it is desired to install outdoor high-voltage equipment and either indoor or outdoor low-voltage equipment. Because of the many applications and arrangements of the low-voltage equipment, only the outdoor low-voltage arrangement will be considered here, together with the 22-kv., 33-kv. and 44-kv. high-voltage side.

The complete outdoor substation installed for 44 kv. is shown in Fig. 1. When used for 33-kv. or 22-kv. service only the insulators and switching equipment need be changed. The substation shown has but one low-voltage circuit, but four duplicate low-voltage circuits may be fed from this substation without any alteration. Outdoor type regulators may be installed on each outgoing circuit. A typical single-line diagram for a four-circuit substation with metering equipment on each circuit is shown in Fig. 2.

The structure is made entirely of galvanized steel and can be used for a high-voltage line pulling in on the structure from the transformer side or from the opposite side. The arrangement with the line coming in from the transformer side is shown in Fig. 3. When the line comes in on the opposite side, the air-break switch at the top is reversed and the two outside phases drop directly to the transformers and the middle phase to the long delta bus at point *A*. The side on which the line comes in depends upon the arrangement required for the low-voltage circuits. It will be noted that the

structure has a double low-voltage bus, which makes it possible to serve two voltages by using triple ratio transformers. When one voltage is all that is required, the double bus feature can be used to facilitate the installation of the totalizing metering equipment when this is used. The height of the transformers is not a limiting factor in the application of the structure, since there is no obstruction above the transformer foundation.

The high-voltage switching and protective equipment consists of an air-break switch, fuse and choke coil, all mounted as a unit on a single channel, which not only reduces the cost of the equipment to a marked degree but also facilitates construction considerably. The switch is controlled from the ground by the remote operating mechanism shown in Fig. 4, installed adjacent to the structure. This type of operating mechanism was adopted as a safety measure in order to remove the operator from the range of falling porcelain and to insulate his body from ground in case of the failure of an insulator on the switch while being operated.

The fuse in the protective unit is of the expulsion type and uses copper wire within a micarta tube for the fuse link. When the fuse link melts under overload, the micarta tube automatically opens, thus preventing the re-establishment of an arc across the tube after the fuse arc is ruptured. The tower is provided with steps and a platform on top to facilitate the replacement of fuses. This type of high-voltage equipment is sturdy and has given service commensurate with many other more expensive types of equipment used to secure similar results.

Open delta capacity is ordinarily provided at substations of this type, but where it is deemed advisable to provide a spare transformer, it is installed on the opposite side of the structure from the main bank and a quick method of connection is provided as shown in Fig. 7.

### Low-Voltage Bus Installation

The lower part of the high-voltage structure serves as a support for the low-voltage bus. This bus and bus structure are so constructed as to facilitate the connection of the individual circuits. The bus proper is made of copper tube and is supported on porcelain insulators. When it is desired to totalize the energy output of the station, the current and potential transformers of the outdoor type are conveniently located on the structure. When it is desired to meter the output of a bank connected in star on the low-voltage side, the double bus feature is used. The neutral bus is carried

*Fig. 7—Connections for use of spare transformer in 44-kv. substation*

in the lower bus position in the star connection. The metering equipment, which is ordinarily composed of a watt-hour and demand meter, is installed in the meter box mounted below the low-voltage bus, the leads from the instrument transformers being carried to the box through conduit.

The low-voltage switching and metering equipment is located adjacent to the high-voltage structure, as shown in Fig. 5 and is housed in a steel cabinet. Each cabinet contains all equipment necessary for an unregulated circuit except the lightning arresters, which are mounted on the pull-off pole. The connection from the bus to the cabinet is made with cable in conduit.

This cabinet can be equipped for all voltages up to 13,200. Cabinets to operate at voltages less than 4,000 can be equipped with disconnecting switches. When cabinets are used for voltages ranging from 6,600 to 13,200, it is necessary to mount the disconnecting switches on the structure as shown in Fig. 6, on account of the greater size of the potential transformers. Each cabinet is fitted with an oil switch, watt-hour meter, demand meter, curve-drawing voltmeter, current and potential transformers for the meters, current transfomers for tripping, disconnecting switches in cabinets except for 6,600 to 13,200 volts, automatic reclosing device and a 200-volt-ampere potential transformer for operating the recloser.

The metering equipment, disconnecting switches, voltmeter and automatic closing device are optional and may be left out of the assembly if desired. To make the oil switch manual it is necessary only to remove the recloser and in its place install a boiler steel plate and face plate as shown in Fig. 8. A 600-volt assembly with the sheet-steel covering removed is shown in Fig. 9 This is complete with all possible equipment with the exception of the curve-drawing voltmeter. The disconnecting switches are equipped with barriers. The recloser is completely automatic and in case of trouble locks out the circuit after one, two, three or four predetermined reclosings. If the trouble clears before the recloser has made the predetermined number of reclosings, the mechanism resets and is ready for another cycle. The recloser is fitted with a trip-free attachment and also with series-tripping equipment. The tripping equipment may be fitted with either an instantaneous or an inverse time limit attachment.

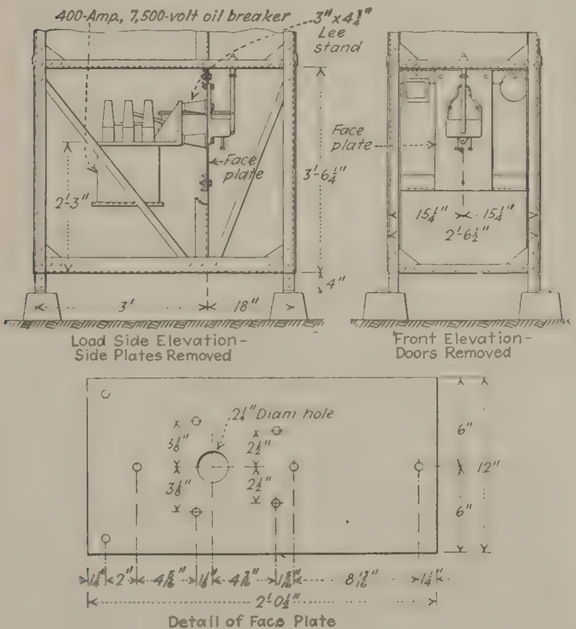

Fig. 8—Feeder switching and metering box without recloser

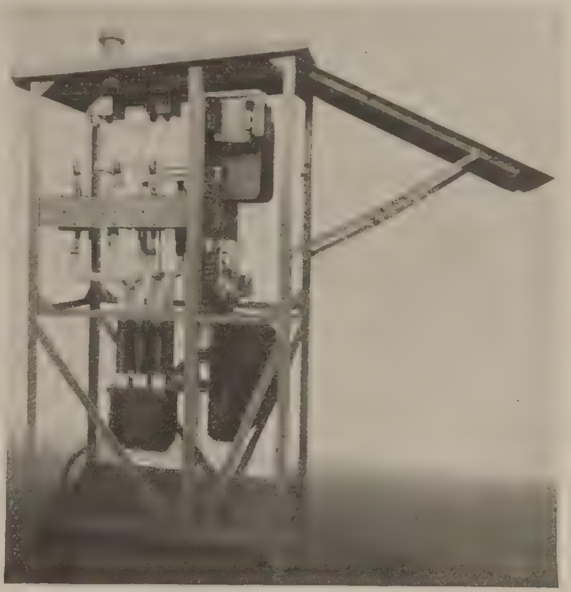

Fig. 9—A 600-volt metering and switching assembly

If it is desired to open the switch by hand, it is necessary only to turn a small lever at the top of the recloser, which trips out the switch and opens the motor circuit, thus preventing it from reclosing. The switch can then be reclosed automatically or by hand. If it is necessary to reclose the switch by hand, this is done by a hand lever at the side of the reclosing mechanism.

The outgoing feeder is pulled through conduit, Fig. 5, to the first distribution pole, where the lightning arrester protection is installed. In the case of a four-circuit substation two poles are used, allowing the conduit runs to be decreased to a great extent.

This type of substation has proved very economical in that it has a very high salvage value, field construction costs are a minimum, since practically everything used in its construction is fabricated in the shops before being shipped to the job, maintenance is low due to the permanent character of the installation and operating costs are low, since the automatic recloser takes care of all trouble beyond the low-voltage oil switch. Any trouble between the high-voltage fuse and the low-voltage oil switch will blow the fuse on the high-voltage structure.

A substation of the type discussed with an all-steel fence inclosing it has a very pleasing appearance. The public respects clean-cut and well-designed construction work such as is employed in these substations. Customers also find in this work a model for any electrical construction work they may be doing and often ask for engineering assistance from the utility organization on the strength of a piece of construction work done by the utility forces. This, of course, should be encouraged rather than discouraged.

## Air-Tripped Steam Dumps Prevent Accidents

EIGHT 750-hp. boilers at the plant of the Salem Electric Lighting Company equipped with mechanical stokers are operated on a schedule requiring the use of steam dumps more than 40 times a day. The dumps are tripped by levers projecting up from the side of the boiler setting and in the past caused a number of accidents to the operator's hands resulting from the short leverage of the control and occasional failure of the locking dogs to function properly, when the levers would fly back with great force and strike the operator. These accidents have been eliminated by cutting off the upper portion of the lever and actuating the lever and dump by the pressure cylinder mechanism illustrated, which utilizes compressed air at 90 lb. per square inch. The device was designed by Owen A. Jackson, chief engineer of the Salem company, and built by James O'Donnell, boiler room engineer, and Thomas E. Moose, machinist of the station staff.

## Merchants' Association Formed to Sell Appliances

By G. A. Kumler
*Assistant Merchandising Manager*
*Portland Electric Power Company, Portland, Ore.*

FAILURE of appliance campaigns to produce the desired volume of sales led the Portland (Ore.) Electric Power Company and the Northwestern Electric Company, the two central stations serving Portland, to conclude that either the public had been campaigned to death or that their merchandising departments were at fault. A plan is now being tried out which it is hoped will bring about increased sales.

It was found that there were about fifteen merchants in Portland dealing in electrical appliances and that three or four of this number were as good merchandisers as the power companies, if not better. Eleven of the merchants were invited to a dinner and after a frank discussion of the situation it was decided to form an association, which was called the "Electrical Appliance Retail Association," to bring about more ethical selling practices and greater co-operation. The association meets once a month and has an executive committee, composed of seven members, which does most of the work. The power companies send out notices and there are no dues. When a campaign is to be carried on all members tie in on several large advertisements, with each member's name appearing. In addition, advertisements will appear in other parts of the paper by individual members. Only approved merchandise will be sold.

The plan has been in effect too short a time to judge of its effectiveness, but it is felt that fifteen retail appliance outlets, all working together, will be able to do a much better selling job than the two power companies working alone.

## Operating Costs of Electric and Gasoline Trucks Compared

DURING preparations early in the spring of 1927 for the Christmas business in December, 1927, the management of the Eleto Company estimated, according to Joseph Husson, president of that organization, that it would require six more ¾-ton gasoline trucks for the delivery of Lord & Taylor and James McCreery & Company's packages in the suburban territory beyond the limits of New York City. This company was operating six ¾-ton gasoline trucks entirely within the city limits and the average mileage of any one of these trucks did not exceed 28 miles per day. The problem was one of purchasing additional gasoline trucks and assigning them to work in the suburban territory and leaving the existing gasoline trucks on the 28-mile city routes, or purchasing electric trucks for city routes and transferring the existing city gasoline trucks to suburban territory.

The problem was solved by purchasing six new electric trucks and transferring the existing short-route gasoline trucks in city work to the suburban territory. The justification for this procedure was based on operating savings of the electric trucks, as given in detail in the accompanying table. A close study of the tabulation shows that all items which would remain the same whether gasoline or electric trucks were used are not tabulated, but are considered to balance off in the comparison. The comparison of the totals of columns (2) and (5) with the total of column (3) led to the purchase of six new electric trucks, four of ½-ton capacity and two of 1-ton capacity. The four ½-ton electrics were used to replace ¾-ton gasoline trucks in package delivery work and the two 1-ton electrics were used to replace ¾-ton gasoline trucks for hotel special deliveries.

The estimated difference in the cost between the ½-ton electric and the ¾-ton gasoline truck in the package delivery service, as previously outlined, is $1.54 per day in favor of the electric. The difference in cost between the 1-ton electric and the ¾-ton gasoline truck on hotel special deliveries is $1.28 per day less in favor of the electric truck. At an estimated approximate saving in favor of the electric of $1.50 per day, the total saving in favor of the electrics would be $9 per day or $2,700 per year of 300 service days.

While this saving led to the purchase of two types of electric trucks, it will not provide any net saving until five years have elapsed on account of the increased initial cost of the electrics as compared to the gasoline trucks. The ½-ton electrics average $3,540 each. For four such vehicles the total cost was $14,160. To this must be

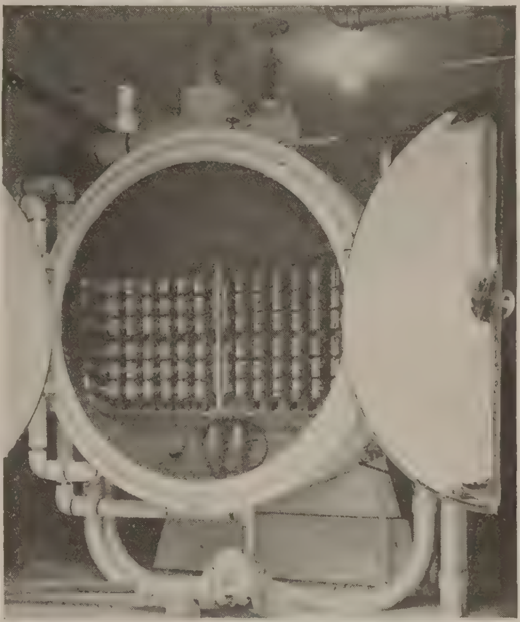
| Less cost per day with electrics | | | $1.54 and $1.28 | | |

added the cost of two 1-ton trucks at $4,395 apiece. This gives a total investment for the six electric trucks and bodies of $22,950. The cost of the gasoline truck equipment, figuring $800 for a second-hand ¾-ton truck put in first class shape and $700 for the body, gives a total cost per vehicle of $1,500 or $9,000 for the six. The cost of the gasoline equipment is thus $9,000, as against $22,950 for the electric truck equipment, making the electric truck equipment cost $13,950 more. At an operating saving of $2,700 per year it will take five years before this difference in cost is balanced off to show net savings in favor of the electric trucks.

A tabulation of maintenance costs, covering a period of seven years and presented by Mr. Husson at the Electric Truck Conference recently held in New York City, will appear in an early issue.

## Electric Boiler Uses Hydro Surplus

FOUR months' experience with an electric boiler at Lewiston last winter proved to the Central Maine Power Company that surplus hydro power from Gulf Island could be economically utilized in the company's auxiliary steam plant for heating its office building and an adjacent hotel and theater. Set against the operating cost of heating by fuel oil at 5 cents per gallon, this hydro-electric energy had a value of from 3.02 to 3.84 mills per kilowatt-hour. Data on the operation of this unit are given herewith, the returns being weighed in the absence of a steam flow meter which will be available for next winter's runs.



*Heating units applied to steam boiler allow flexible operation*

The boiler consists of an International Engineering Works unit 66 in. in diameter x 19 ft. over all, containing 72 tubes 3 in. x 16 ft. each. It was built for a working pressure of 125 lb. and is rated at 120 hp. It is equipped with 1,200-kw. heating units divided into four 440-volt circuits and automatically controlled by four pressure governors and a Copes water regulator. The General Electric Company furnished the electrical equipment. A saving of about $25 per day over fuel oil, including labor economies, is being attained, according to R. D. Morrison, industrial engineer of the utility.

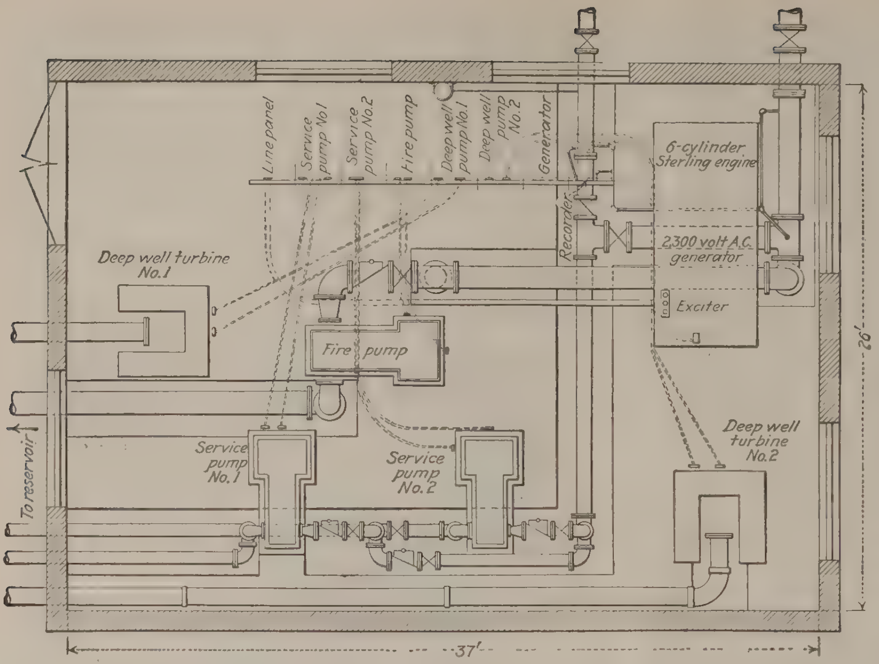
## for Water

By H. A. Tolburg

*Superintendent of*
*Water Department, Kewanee, Ill.*



*Plan of Monmouth pumping station*

IN DESIGNING and building the new municipal water plant for the city of Monmouth, Ill., it was decided to make the installation as nearly perfect as possible in order to free the public from all unnecessary expenses in future operation and at the same time place the city in a lower class of insurance risks as classified by the Illinois Inspection Bureau. Another aim was to remove the water department from the curse of local politics as much as possible by reducing the labor requirement in operation. This was all accomplished by the installation of full automatic electrical control of all pumps and motors.

The pumping plant includes two deep-well turbine pumps, two 3-in. horizontal centrifugal service pumps, one 6-in. horizontal centrifugal fire pump, all pumps being driven by 2,300-volt, slip-ring induction motors. Stand-by equipment consists of a 90-kw., 2,300-volt, 60-cycle, three-phase generator direct connected to a 225-hp. Sterling gasoline engine having starter, oil gages and speed controls.

The two deep-well pumps deliver 1,000 gal. per minute each into a 750,000-gal. reservoir, the service pumps deliver 450 gal. per minute each into the system and the elevated tank, which tank has a capacity of 125,000 gal. with a total head of 140 ft. The fire pump delivers out of the reservoir into the system at two speeds, the first 1,000 gal. per minute at 80-lb. pressure and the second speed 1,500 gal. per minute at 105-lb. pressure. The fire pump is served by two control panels, one panel being full automatic, started from either the central fire station or the pumping station by push-button controls, the central fire station being ½ mile from the pumping station. The other panel which controls this pump is a manually operated one of special design and is used in case of failure in the automatic control circuits. The piping from the fire pump to the mains is so arranged that as soon as the pressure is raised above the elevated tank pressure a swinging check valve closes and cuts out the elevated tank, and as quickly as the pressure is cut down to the elevated tank pressure the check opens and the tank is again floating on the distribution system. The switchboard was designed by the Sundh Electric Company, Inc., Newark, N. J.

The automatic features are controlled by pressure regulators and float switches placed in the reservoir and on the distribution system. The float switches are arranged to give a 4-ft. regulation in the reservoir and these switches control the two deep-well pumps. The pressure regulators on the service pumps are so arranged that should the demand be greater than the capacity of the No. 1 pump, then the No. 2 pump will cut in automatically and stay on the line until the elevated tank is full. These pumps are arranged on the board so that they can be alternated and either of them be used as a stand-by. The piping of the service pumps is laid out in such a manner that they can be operated in series to assist the fire pump in case of an extraordinary demand. The elevated tank is protected from being exhausted of its water supply by a pressure regulator on the switchboard so that an alarm will ring should the water supply become dangerously low.

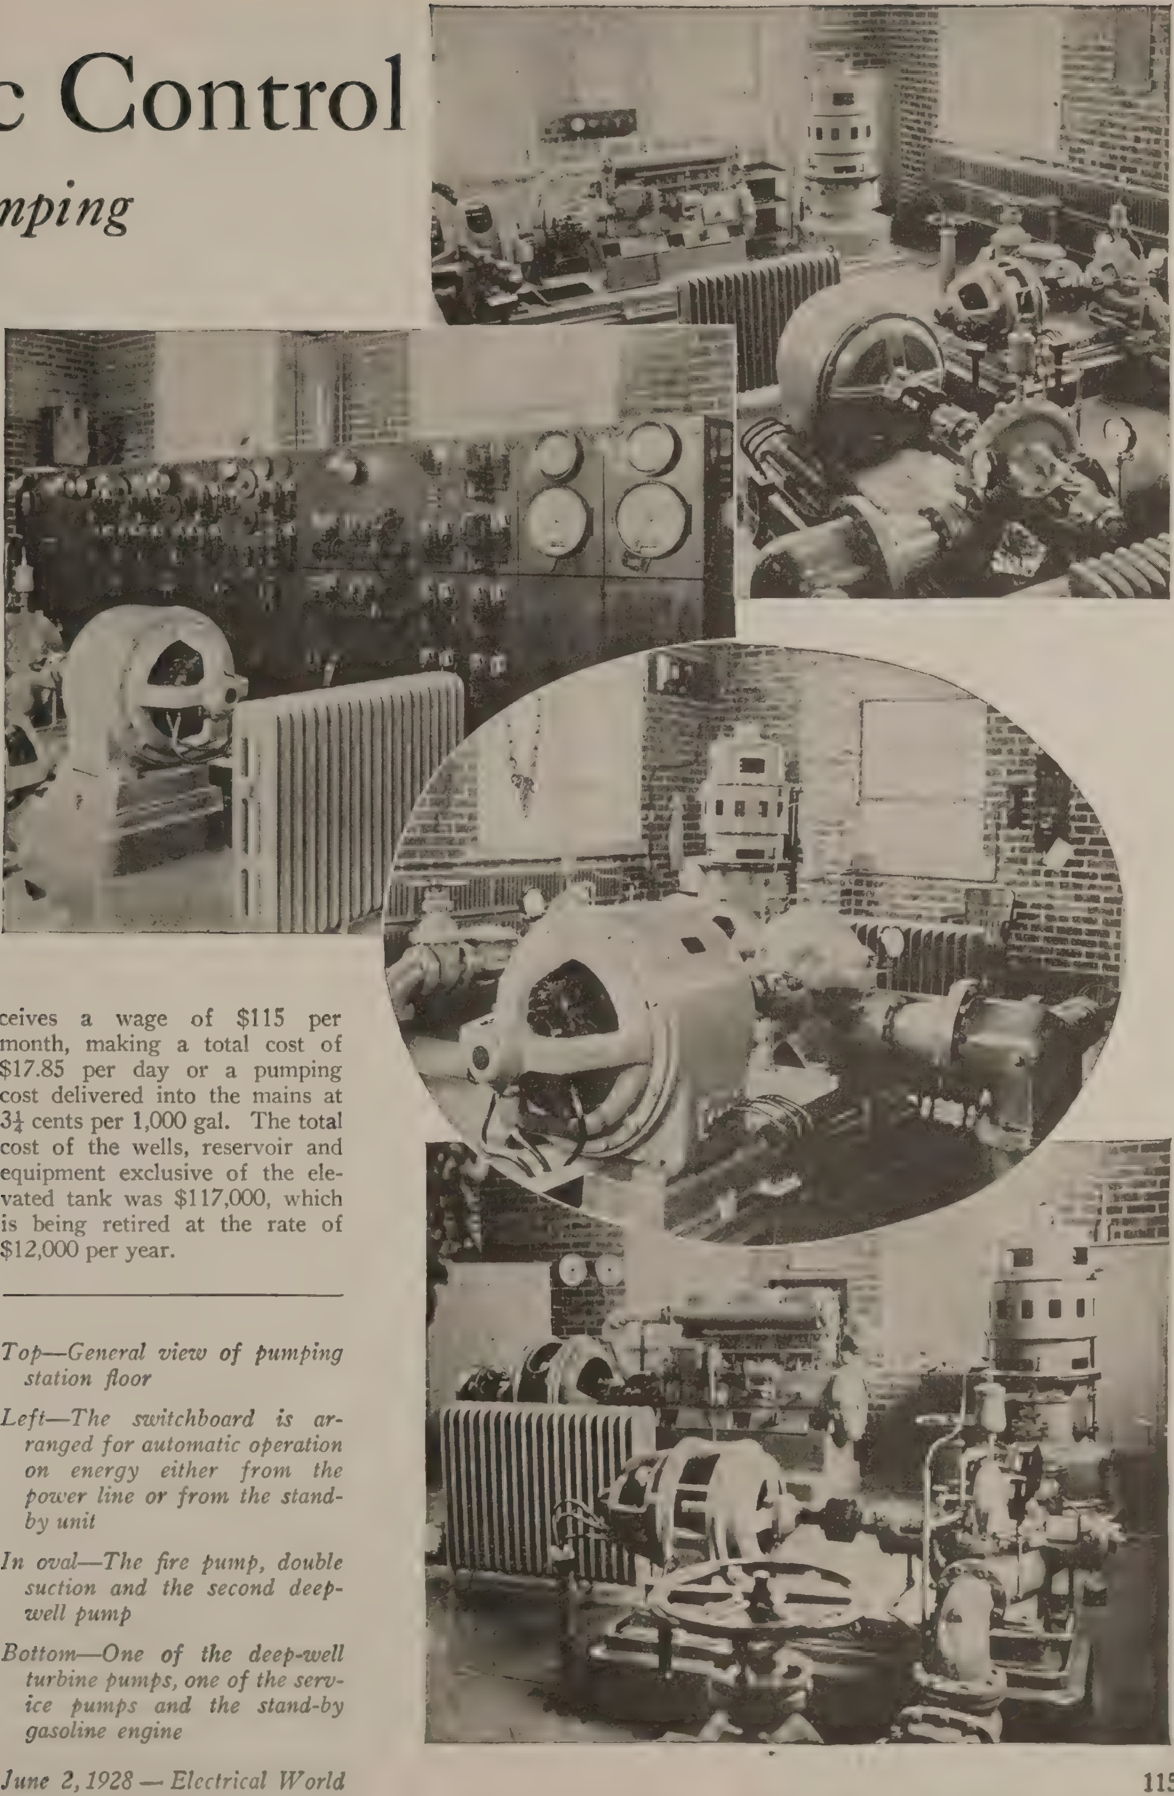
### Protected by Interlocking Relays

The switchboard in all consists of ten panels arranged as shown on the drawing. The incoming line panel is provided with one three-pole, double-throw oil circuit breaker equipped with inverse time-limit overload in each phase, undervoltage release and auxiliary contact to close and ring the alarm on panel No. 4 when the breaker opens on either side; this switch is interlocked so that it is impossible to put the line and generator on the buses at the same time. There is also provided on this panel one reverse phase relay of undervoltage release type with necessary interlock relays to open the oil circuit breaker in case of reversal or failure in line voltage. There are mounted on panels Nos. 9 and 10 two General Electric flow meters, indicating, recording, and integrating gallons per minute.

Prior to the installation of this equipment in the pumping station it was costing the city of Monmouth $45 per day for fuel and labor, pumping 490,000 gal. per day from three wells with air compressors. Today it is pumping a total of 550,000 gal. at a power cost of $14 per day and one attendant part time, who re-

# tic Control

## *Pumping*



ceives a wage of $115 per month, making a total cost of $17.85 per day or a pumping cost delivered into the mains at 3¼ cents per 1,000 gal. The total cost of the wells, reservoir and equipment exclusive of the elevated tank was $117,000, which is being retired at the rate of $12,000 per year.

## *A Partnership*

Successful principles upon which the purchasing of a prominent electrical manufacturing company has been organized with price cutting eliminated

By Edward L. Johnson
*Purchasing Agent Black & Decker Manufacturing Company, Towson, Md.*

BECAUSE of the general interest which has been developed in the subject of price cutting and in the ethics and economics of purchasing, in the series of articles that have been appearing in the Electrical World, I believe that a statement of the policies of a manufacturer's purchasing department might be of interest. It may serve to contribute another sidelight on this discussion.

In establishing purchasing principles for this company, we have strongly adhered to the policy that the supplier of any commodity we use is entitled to a fair margin of profit, even as we, as manufacturers, expect a fair profit on merchandise we sell to our customers. In the selection of material for our own products we have always endeavored to consider first and foremost the quality of these materials in relation to their application and requirements, letting the cost to us be the secondary factor. We think this policy, together with the proper manufacturing equipment and labor, is responsible for the general reputation of our product.

### Studying Sources of Supply

Furthermore, we have always paid considerable attention to the sources of supply with which we deal or wish to deal, making special efforts to cultivate the friendship and good will of our suppliers. We have not confined this practice to their sales forces alone, but, by frequent plant visitations, have made the acquaintance of their factory organizations, whom we consider the men behind the guns. In other words, we look upon our main sources of supply as departments of our own business. Merely because their plant is in another city, operating under another name, does not eliminate the fact that they are producing parts for use in Black & Decker tools. By this practice we are able to gather quite a good deal ot knowledge concerning materials and parts purchased for our tools, as well as the conditions and difficulties surrounding the manufacture of them.

If a purchaser knows the commodities he is buying and the factories producing them, he knows when he has prices that are in keeping with production costs and a fair amount of gross profit and it is not necessary to follow the practice of securing competitive bids on a wholesale scale. When we feel that the price of a commodity which we have been buying from an old source of supply is too high, considering market conditions, we take the question up immediately with this source, rather than go out after competitive bids and remove the business to a new source. In such cases, we very often visit the plant of the seller, at which time all cards are laid on the table, cost figures gone over and usually an agreement reached that is satisfactory to both parties. Our suppliers welcome this policy, as they realize that we are willing to work along with them and are playing the game on the Golden Rule basis.

We want all our suppliers to make a fair profit, but, at the same time, hold costs down to a minimum. We often help them accomplish this by suggesting different means of handling and routing our work and by increasing schedules, so as to enable the seller to buy or contract for raw materials in larger quantities. These methods have generally resulted in economies to us as a purchaser without affecting the gross profits of the seller. When the purchaser and seller have the proper contact with and confidence in each other, there is not very much need of competitive bids, or business being awarded on a cold-blooded price basis. Furthermore, changing sources of supply with every order placed or requirement released is costly to both the seller and the purchaser. Neither one has had the opportunity to learn much about the personnel, plant operation, etc., of the other, and without this knowledge they cannot work together to the best advantage.

In many cases, we have been dealing with the same companies supplying us with certain commodities for a period of ten years and more, yet have been able consistently to produce our own equipment at lower costs and market it at a lower price each year to our customers. This is due, in a measure, to our ability to lower our own production costs from time to time, but we have also been aided materially by our suppliers working with us in an effort to furnish our materials at the lowest possible price, consistent with quality of material and their making a fair profit on the sale of same. No business relations can be profitable unless both parties reap benefits from the transactions.

### Fairness Insures Co-operation

We have dealt with some foundries for years without moving a pattern and feel confident we have fared better than if we had followed a policy of shifting our work from place to place, merely because some one else offered a little cheaper price than we were paying. We know, nearly as well as the foundries, what it costs to produce our work, the amount of metal required, the number of molds it is possible to get from a machine per day and the approximate amount of foundry rejects. From what they tell us and what we see by visiting their plants, we know what their overhead is and can tell when they are selling at the right price with due regard for their profits.

Through this policy with our suppliers we have got co-operation and assistance in emergencies which we could not demand or hope to get on short acquaintance from companies which we were making fight to the last ditch to get our business. In many cases our principal sources have worked overtime and Sundays to get our stuff out and help us out of a jam, without raising prices a penny. Why? Because we play the game fairly with them and they are above taking an unfair advantage of us in such emergencies.

### Mutual Protection

There is another angle to this co-operative procedure which bears consideration. Whenever we reach a point where competitive conditions arise in our own field and we have to alter prices on our products we feel that the first move is to study our own equipment and facilities, to see what can be done toward effecting economies in our own plant. The results and benefits of these studies are very often passed on to our suppliers and aid them in their own production methods, which, in turn, reacts to our adavntage as well as the sellers'.

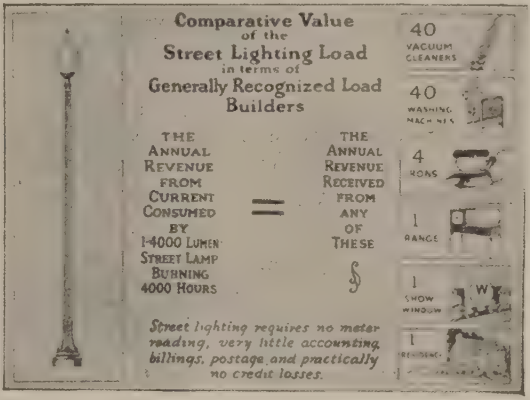
Today we are in the midst of a buyer's market, but this condition will not last forever. Sooner or later we are going to have a return of the seller's market, the same as existed not so very long ago. It is then that we expect to reap the real benefits of our Golden Rule policy and fair play toward our sources of supply. When material and shipments are hard to get and we need prompt deliveries, we believe most of our suppliers will be glad to come through and help us out, not forgetting our treatment of them during the buyer's market period. The purchaser who runs a regular auction sale with his buying is sooner or later going to get it in the neck, because those sellers who are now being ridden over roughshod are not going to forget. When the seller's market returns, these auction sale operators, as well as the companies they represent, are surely going to pay the freight, reaping as they have sown. We may be all wrong, we may find that we have overestimated the value of a policy such as we have fostered, but certainly it has not been proved to us yet, and past history does not indicate that it will.

### Profitless Operation Disastrous

I consider it very poor practice for manufacturers to cut their prices deliberately to secure business, with no regard for profit. These fellows are, as I call it, buying business, with no profit to themselves, and are inevitably headed for receivership and, ultimately, the rocks. The successful manufacturing plant must, in figuring its prices, take into consideration material costs, labor costs and factory overhead, as well as general sales and administrative expenses. It owes this not only to itself, but to the stockholders of the company, to whom it must ultimately answer. In the final analysis, the officers of any company are only men who are intrusted with stockholders' money which they must invest profitably, and unless they give proper consideration to this fact and can show a certain percentage of profit on each sale they can never hope to build up a healthy financial condition within their organization and increase the value of their company's stock or other securities. Unless this is accomplished, they must eventually come to grief.

## Revenue Value of Street Lighting

ADEQUATE street lighting was stated by L. A. S. Wood, at the recent annual convention of the Missouri Association of Public Utilities, to be the proper remedy for the crimes and accidents occurring during the hours of darkness. It was pointed out that with a well-balanced rate schedule and suitable methods of finance the sale of street-lighting service is a profitable branch of the public utility company's business and that the value of the street-lighting load is constantly increasing. Although the hours of burning may vary with the seasons, they total 4,000 per year, which is undoubtedly a longer period than any other load, except a few of special nature which exist in some metropolitan areas. The load factor, said Mr. Wood, is approximately 46 per cent for a 4,000-hour schedule, and while it may include part of the evening peak, it also ranges through the midnight to morning valley. Revenue from street lighting is assured through periods of industrial depression, as well as prosperity. There are rarely any bad debts or loss of revenue from this source.



Comparative Value of the Street Lighting Load in terms of Generally Recognized Load Builders
The Annual Revenue from Current Consumed by 1-4000 Lumen Street Lamp Burning 4000 Hours
=
The Annual Revenue Received from any of These
40 Vacuum Cleaners
40 Washing Machines
4 Irons
1 Range
1 Show Window
1 Residence
Street lighting requires no meter reading, very little accounting, billings, postage and practically no credit losses.

*Comparative load value of street lighting*

The scope of the street-lighting load was foreseen as becoming continually wider, since in addition to street lamps the modern city requires traffic signals, warning beacons, underpass and viaduct lighting and highway lighting, all of which present additional and constantly increasing opportunities for augmenting the central station's revenue. More show-window lighting invariably follows improved street lighting. Inadequately lighted stores are dim and unattractive in comparison with the well-illuminated streets, and thus a source of additional revenue is added when an improved street-lighting system is installed. "When compared with other load-building services which the central stations are aggressively promoting street lighting is in a class by itself," Mr. Wood concluded.

## Loads to Be Expected from Radio Equipment

HOW much does radio reception contribute to the per-customer usage of electrical energy? This is a question which has probably arisen in the mind of every commercial department head who is seeking ways of making his domestic customers bring a bigger return on the investment and operating expense required to serve them. In the past several evidences have been presented to indicate how radio reception has increased use of lights in the home. Following are some figures that have just been collected by *Radio Retailing* from radio manufacturers which may be the basis for calculating the direct effect of radio equipment on energy consumption:

> For example, the average demand of eight different competitive receivers is 65 watts. Set A requires approximately 40 watts; set B (six-tube), 34 watts; set C, 45-50 watts; set D (six-tube), 50-55 watts. Sets E and F, using one of the original alternating-current tubes, require considerably more power and bring the average up to the figure quoted.
>
> Power speakers, of which three well-known types were investigated, draw even more current. Type A power cone demands 100 watts and type B around 190 watts.
>
> The average A power unit takes 110 watts, the average trickle charger uses 20 watts, "socket-power" B units average 25 watts. Receivers using battery tubes with rectifying equipment for A, B and C supply average 100 watts.

As *Radio Retailing* points out, "It can easily be seen that it is not safe to multiply the total number of receiving sets by one average figure because of the differences in demand." The type of equipment and hours of usage must be taken into account.

## *Reinvesting Called Preferreds*

*To the Editor of the* ELECTRICAL WORLD:

I want to congratulate you on your editorial entitled "Reinvesting Called Preferreds." It has seemed to me that utilities, which are dependent on the good will of the general public, make a mistake in calling their preferred stocks without at least permitting the owner to participate in the new preferred issue.

There are several cases in hand, one of which is Duquesne. Duquesne called its 7 per cent preferred and issued a new 5 per cent preferred without any chance for the owner of the old preferred to exchange for the new preferred. The same action is being taken by Engineers Public Service, and presumably will be taken by Niagara Falls Power.

While I can appreciate that it may cause delay and book-keeping, it would seem comparatively simple to state to an owner of a preferred which is to be called that the amount due him at the called price of the old stock will, upon request, be applied on the purchase of shares of the new issue at the price at which it is to be marketed. If a fraction of a share results, the owner of the old stock should be given the privilege of making up the difference so that he would receive whole shares. This would benefit the owner of the preferred stock in several ways:

First—He would be saved the immediate payment of income tax on the appreciation of the old stock.

Second—It would save the owner of the old stock the broker's fees in purchasing the new stock.

Third—It would enable him to get the new stock at the issue price, which often jumps before the old owner has a chance to get a whack at it.

It should save the utility some of the cost of the bonus which it allows the broker who handles the entire issue. Certainly such action would create good will, whereas the present method is creating more bad will than the utilities appreciate.

H. R. SARGENT.

Bridgeport, Conn.

## *Opposes Trading After Receipt of Bids*

*To the Editor of the* ELECTRICAL WORLD:

I have been reading the various articles on price cutting in the ELECTRICAL WORLD. I do not think a purchasing agent, if he buys on an ethical basis, can initiate price cutting. This responsibility rests entirely with the manufacturer or jobber, as the case might be. My idea of ethical purchasing methods is to give all manufacturers or jobbers who are qualified to supply the material wanted an opportunity to quote. When quotations are received and tabulated the lowest bidder, quality of material considered, should be given the business.

A purchasing agent should never give any one bidder an opportunity to revise his prices or trade in any way in an attempt to throw the business to one particular man or manufacturer. Should this practice be pursued the purchasing agent's firm will eventually pay higher prices for the material. After the business has been placed I do not think it is the prerogative of the purchaser to tell the losing bidders why they lost the business.

The above is in direct conflict with the recommendations in your article and no doubt you have good reasons for your recommendations, but why should the purchaser act as a police officer in detecting the whys and wherefores of lost business for the manufacturer?

When a manufacturer quotes a price on his products I assume that the price is based on his manufacturing cost plus development or research and sales expense plus a legitimate profit. Therefore, when business is lost it can be assumed that the price quoted was out of line with other bidders. It is, therefore, the problem of this company to ascertain what is wrong within its organization. Information regarding the price paid to the successful bidder and the firm's name, as I see it, can be of no value to it.

Price cutting and price profiteering are as old as the ages. I believe they will always be with us, and their extent will be limited only by the law of supply and demand. However, I believe that the ethics of purchasing as a whole can be greatly improved by the elimination of trading after bids are received, and the seller can aid materially by refusing to adopt a trading attitude.

The manufacturer, in my opinion, is solely responsible for these trading or price-cutting tactics. I will venture that there is not a purchasing agent in the country who does not hear daily this remark from salesmen submitting bids: "If my prices are not in line, please give me a chance to revise them." This immediately gives the purchaser the idea that this particular bidder has not submitted prices to which the purchaser is justly entitled.

How much better it would be to all concerned if the seller would not request an opportunity to revise prices, and if such requests are made the purchaser should firmly state that no revisions would be accepted after bids were tabulated. The pursuance of such policies by seller and purchaser would put every one on an equal basis.

I might add that the purchasing policy as outlined above has been followed satisfactorily for many years by the two companies I represent as purchasing agent and I have yet to find a manufacturer who does not agree with us that it is equitable to all concerned. F.

[The recommendation referred to was that where bidders are called back and asked to reduce the price the salesman should demand that he be shown the other bids as evidence that he is really high. "Firm bidding" has been urged, however, as the only effective cure for price cutting, a steadfast one-price policy, the business to be placed to the lowest figure on the original bids.—EDITOR.]

# Digest of Electrical Literature

## Hydro-Electric Development and Steam Equipment

*Combustion and Heat Transfer.*—R. T. HASLAM and H. E. HOTTEL.—The transmission of heat at moderate temperature levels is considered by the author to represent a fairly complete chapter in the subject of engineering design. This discussion endeavors to present a record of the present status of knowledge on heat transmission by radiation, including some recent developments in the theory of non-luminous gas radiation and some new ideas on radiation in powdered coal plants. A mathematical discussion is offered of the theoretical factors involved. The treatment covers radiation from suspended matter in powdered coal flames, from non-luminous gas, from luminous gas flames, between finite and solid surfaces, simultaneous radiation of gases and suspended solids, application of mechanisms described to furnace design and several methods for the solution of furnace problems. Emissivity of the flames due to suspended coal particles, to gas radiation and to the presence of solid carbons are covered also.—*Transactions of the American Society of Mechanical Engineers,* January-April, 1928.

*The Yokawa Automatic Hydro-Electric Power Station.*—U. VETSCH.—This hydro-electric generating station is a part of an extensive power supply scheme in Japan and may be started up or shut down by switching in or tripping the transmission line connecting it to the main power station. Periodic inspections are made, but other attention is unnecessary. The control arrangement by means of which the generator and switching operations may be performed and the provision for unusual conditions necessitating the automatic shutdown of the plant are given. External and internal disturbances have been fully allowed for in the planning of this station.—*Brown Boveri Review (Switzerland),* May, 1928.

*The Clinkering of Coal Ash as Related to Laboratory Fusibility Determinations.* — A. C. FIELDNER, W. A. SELVIG and P. NICHOLLS.—As the result of an investigation of 21 kinds of coal with fusion temperatures from 1,990 to 2,930 deg. F. and including determinations as to composition, distribution and fusibility of ash, conclusions regarding the clinkering characteristics of these coals were made by the authors. Float-and-sink tests were made with the coal, sulphur forms were determined, analyses of the ashes prepared and the results checked. It is concluded that the quantity of clinker formed decreases as the rate of combustion increases, although the density and fusion of the clinker pieces are greater at the higher rate. The rate of decrease in quantity with rate of burning becomes less when the coal ash and fusion temperatures are low. The quantity of clinker formation has a fairly definite relation to the softening temperature of the coal ash as determined by the standard gas furnace method. No distinct relation was found between the shortening of the flowing temperature interval and the formation of clinker scale.—*Transactions of the American Society of Mechanical Engineers,* January-April, 1928.

## Generation, Control, Switching and Protection

*Stress Analysis in Electrical Rotating Machinery.*—M. STONE.—The continuous trend toward larger and higher speed power generation units has, according to the author, required detailed attention to new design problems predominantly of a mechanical nature. Improvements in the knowledge of the behavior of the materials of construction and a more accurate estimation of stress conditions by detailed analysis have been accomplished in recent years. In this discussion the author has considered the methods available for stress analysis. The experimental lack of coincidence of the calculated critical speed and the observed vibration peaks is said to be affected by any flexibilities in the vibrating structure that are not properly evaluated, and the flexibility of bearings and bearing pedestals may be sufficient to lower the calculated critical speed by as much as 50 per cent.—*Sibley Journal of Engineering,* April, 1928.

## Transmission, Substations and Distribution

*Large Single-Phase Transformers.*—A. WINIGER.—The author offers a detailed description of the transformers used to step down the 132-kv., single-phase supply of the Swiss railways to 66 kv. At 16⅔ cycles the continuous rating of each transformer is 9,000 kva. at 0.75 power factor. A ten-minute overload with 13,000 kva. is permissible. The machines are of the two-legged circular coil type, with the 132-kv. winding next to the core and the 66-kv. winding with its five middle taps per leg on the outside. The laminations of the core are paper insulated, the legs have smooth ends for butt-joints with the extra heavy yokes, and the finished core is completely lacquered to avoid any action between the steel and the oil and to prevent rusting in the shops. Heavy nickel-steel press bolts hold the core structure together and extend on top to engage with the domed cover, making the entire active part of the transformer cover-suspended. The winding is made of multi-layer paper insulated copper strip, but to give the coils greater stability and to avoid shrinkage the wire insulation is impregnated with artificial resin. The end turns will stand line voltage for five seconds. The oval, all-welded tank is heavily reinforced to stand either an internal pressure of 28 lb. or a vacuum of ¼ in. mercury. The oil conservator is mounted on the tank, but is clear of the cover, making it possible to untank the transformer with a minimum of trouble. Some distance away from the tank is installed a large battery of tabular radiators, and a 4-kw. motor pump circulates the oil between transformer and cooler. — *Bulletin de l'Association Suisse des Electriciens,* April 22, 1928.

*Short-Circuit Risks on High-Tension Networks.*—J. BIERMANNS. — A theoretical consideration of the electrodynamic forces encountered in short-circuit conditions on high-tension networks has been offered by the author and supplemented by practical observations regarding such phenomena. The short-circuit forces on conductors, heating of conductors carrying the short-circuit current, oil circuit breaker stresses due to switching out a short circuit, devices utilized to limit the magnitude of the short-circuit current and similar pertinent factors have been considered.—*A.E.G. Progress,* April, 1928.

## Units, Measurements and Instruments

*Bridge for Measuring Small Time Intervals.*—J. HERMAN.—A bridge circuit for measuring time intervals from about one ten-thousandths of a second up to several seconds is described and its operation explained. The device is said to be fairly accurate and easy to operate and gives the results of measurements in fractions of a second directly. The operation consists merely of opening or closing a key repeatedly and securing a balance by observing a meter. The balance is secured by turning one or more dials which are calibrated in fractions of a second. Suggested applications include: Measuring the functioning times of electromagnetic switching arrangements; measuring propagation time at different frequencies; studying the operation of a machine with a view to improving its speed; maintaining proper adjustment of relays, cicruit breakers, etc., in power circuits; determine rate of acceleration of motors, and in psychological tests, the response of individuals to certain stimuli.—*Bell System Technical Journal,* April, 1928.

*Magnetic Leakage and Fringing Flux Calculations.*—WALTER L. UPSON and ERNEST L. FURTH.—The authors have endeavored to develop an empirical method for determining leakage and fringing fluxes in an electromagnetic system. Certain assumptions are made in regard to the reluctance of the iron parts of the magnetic circuit and the leakage and fringing components of the flux following the paths of geometric shape. Formulas are derived for leakage and fringing fluxes as percentage of the main flux which crosses the gap from the pole face for two cases, that of a pole core of circular section and of one of rectangular section. Calculations of these fluxes in percentage of the main flux are given over a convenient range of gap lengths, coil lengths and distance of coil from pole face. It is demonstrated that both leakage and fringing depend to a considerable extent on all these factors. Calculations are made to determine the flux density at various points along the core length and these show a wide variation in density in accordance with the dimensions of the magnetic circuit. An experimental check was made of certain of the calculated results.—*Journal of the American Institute of Electrical Engineers,* May, 1928.

## *Electrophysics, Electrochemistry and Batteries*

*The Aluminum Electrolytic Condenser.*—H. O. Siegmund.—After outlining the development of the valve or polarizing effect of aluminum metal, when operated as an anode in certain electrolytes, the author discusses the operating characteristics of the aluminum condenser. There are two common conditions affecting the life of these devices that must be controlled, the chemical action of the electrolyte on the electrodes and the film, and the corrosion of the anodes. An ammonium borate solution having a specific resistance of 225 ohms per cubic-centimeter has proved to be satisfactory. The author has given consideration to the electrical qualities of films on aluminum, capacity of aluminum films, effect of impressed voltage on capacity, losses in aluminum cells and their effect on electrical impedance, commercial applications and designs of electrolytic condensers, the anode construction and material, the negative electrode, the prevention of contamination in manufacture and installation, the composition of the electrolyte, the relation between voltage of film formation and operating voltage, capacity and resistance characteristics, corrosion of condenser anodes, and the life of aluminum condensers. *Report of American Electrochemical Society,* April, 1928.

*The Effect of Trivalent Chromium and Iron on Chromic-Acid Chromium Plating Baths.* — R. Schneidewind, S. F. Urban and R. C. Adams, Jr.—It has been found that the current efficiency of chromium deposition from chromic acid baths is a straight line function of the logarithm of the current density. The slope and position of this line are affected by the temperature and composition of the baths. In baths containing chromic acid and sulphate ion bright deposits are obtained on copper between limits corresponding to certain current efficiencies. In cases of other metals the range of current efficiencies yielding bright plate may be narrower than that for the baths mentioned. Heavy deposits on all metals are best obtained at 12 to 14 per cent current efficiency. Other things being equal, increasing the concentration of trivalent chromium and iron does not appreciably change the relationship of current density to current efficiency. However, the range of current densities producing bright plate is markedly contracted.—*Report of American Electrochemical Society,* April, 1928.

## *Traction*

*Locomotive with Vertical Motors.*—H. Furst.—The Austrian Federal Railways operate a novel type of express locomotive on their electrified valley lines, which has given unusually good performance. The new feature is that of individual motor drive for each axle by means of four vertical shaft motors, transmitting their power over spiral type bevel gears and special flexible couplings to the drivers. Each motor is rated 410 kw. at 855 r.p.m. and operates on 385 volts, 16⅔ cycles, giving the engine a top speed of 53 miles per hour. An oil-cooled transformer of 1,550 kva. output, 15,000 volts primary, with sixteen secondary voltage taps, is mounted midway between the solid frame of the locomotive. On each side of the transformer are arranged eight compressed-air-actuated contactors to regulate starting and running voltage without current interruption.—*Elektrotechnik und Maschinenbau,* April 8, 1928.

## *Telegraphy, Telephony, Radio and Signals*

*Grid Current Modulation.*—Eugene Peterson and Clyde R. Keith.—The term grid current modulator as used in this article refers to those vacuum tube circuits in which modulation is initially produced in the grid circuit of the three-electrode vacuum tube due to the non-linear grid-current grid-voltage relation. Comparison with a representative plate current modulator using the same tubes and the same plate potential shows that by modulating at maximum efficiency in the grid circuit and using the plate circuit solely for amplification the maximum power output is increased about eight times, the power efficiency is increased about five times and the ratio of sideband output to signal input is increased approximately three times. Under these conditions it is said that more carrier input power is needed for the grid than for the plate modulator. This improved performance has been made possible by a detailed study of the fundamental processes involved and by a design of the tubes and associated equipment such as transformers and filters to permit these fundamental processes to operate to their best advantage. The article concludes with an application of the fundamental principles involved to an experimental carrier telephone system in which the operating features of tubes, filters and transformers are discussed.—*Reprint B-292 Bell Telephone Laboratories, Inc.*

## *Miscellaneous*

*Pipe Bends Made by New Process.*—Production of short-radius pipe bends by a new and unusual process has recently been inaugurated by an American manufacturer. The bends are really short arcs of pipe made on a production basis in a standard series of sizes, and can be made of any bendable material in any thickness. It is stated that the manufacturers anticipate a definite series of bends of long and short radii to be capable of taking care of practically every requirement in the way of a fitting for welded piping. A standardized shape makes available to the consumer the advantages incident to mass production, including quick delivery, low cost and small inventory. The manufacturing process involves a furnace, special mandrels and a hydraulic press. The ram from the press travels over a long steel shaft, fixed into the stationary head of the hydraulic cylinder. Over this shaft a straight length of pipe is slipped until it strikes a flat ring fixed on the nose of the ram. After the straight pipe is placed on the shaft a horn-shaped mandrel is attached to the forward end of the shaft by a double-threaded turnbuckle coupling. The ram then moves the pipe onward until the forward end binds against the turn at the base of the mandrel. A gas furnace is used in this process to render the pipe plastic. The pipe is pushed over the mandrel as fast as it is hot enough to work. The design of the mandrel determines the curvature of the bend and the wall thickness, and variations from a straight bend to a wide coil are obtained by the location of the heat during the operation.—*Iron Age,* April 5, 1928.

*Tensile Properties of Soft Rubber Compounds.*—R. F. Tener, S. S. Kingsbury and W. L. Holt.—The results of tensile tests upon six rubber compounds when subjected to temperatures ranging from minus 70 deg. to plus 147 deg. C. are reported by the authors. These investigations indicate that temperature has a pronounced influence upon the tensile properties of the rubber. Within the lower limits rubber becomes rigid with an increased tensile strength, while at high temperatures it possesses practically no tensile strength whatever. This behavior was characteristic of all the specimens investigated. Differences due to compounding ingredients are, according to the authors, differences in degree rather than in kind. The magnitude of the changes in rubber compounds due to temperature shows that the effect of temperature should be given consideration in the design of rubber articles which are to be used at other than normal ranges.—*No. 364 Technologic Papers of the Bureau of Standards.*

# News of the Industry

## All in Readiness for the Big Atlantic City Convention

With hundreds of delegates from distant points already on their way and with the manufacturers' exhibition receiving its finishing touches, everything as the week closes points to a crowded and most successful convention of the National Electric Light Association at Atlantic City next week. Monday will be given over mainly to registration and greetings, with the reception to President and Mrs. H. T. Sands at 9 p.m. in the Million-Dollar Pier ballroom, followed by dancing. On Tuesday, Wednesday, Thursday and Friday mornings at 9.30 o'clock and Wednesday and Thursday afternoons at 2.30 the general sessions will be held on the Million-Dollar Pier. On Tuesday afternoon the four national sections meet—the Accounting at the Hotel Traymore, the Commercial at the Chalfonte-Haddon, the Engineering and Public Relations on the pier, while the public policy committee will have its open meeting on Wednesday evening at 8.30 in the ballroom, with music by B. A. Rolfe's orchestra and Richard Crooks, a well-known tenor.

The program of the business sessions was printed in the ELECTRICAL WORLD for May 19 (page 1031). Among the entertainment provided are included a ladies' card party on Tuesday afternoon at the Traymore, dancing on Tuesday and Thursday evenings, golf, croquet and dart throwing for "ladies' day" at the Seaview Golf Club grounds on Wednesday, and a special entertainment on Thursday evening in connection with the dances. Thursday afternoon has been left open.

The manufacturers' exhibition has increased in size from 41 participating companies in 1908 to 209 this year and from 3,650 sq.ft. to 81,082 sq.ft., with the size of displays limited and some manufacturers unable to get space.

News has been received at headquarters that Governor Dan Moody of Texas will not be able to make the announced address on "Decentralization of Industry."

## New York Water-Power Act Is Sustained

A decision handed down at Albany, N. Y., on Tuesday of this week by the Court of Appeals, the highest state tribunal, in Horton vs. the Public Service Commission and the Niagara, Lockport & Ontario Power Company, sustains the constitutionality of Section 624 of the state conservation law. This was a part of the original water-power legislation passed under the administration of Governor Nathan L. Miller in 1921 and in effect provides that a corporation organized for the production of heat, light or power owning the major portion of the head and volume of the usable flow of a stream and wishing to make a power development may acquire by eminent domain such additional property as may be needed to complete its project. This provision was held to favor large power companies at the expense of small ones.

The law was attacked on the ground that it was unconstitutional. The matter had been pending since 1924, at which time application was first made to the Public Service Commission to take advantage of the provisions of the law, and the decision is regarded as a most important one in utility circles.

With the Horton case disposed of, the Public Service Commission may now place upon its calendar and take testimony in the matter of the application of the Rochester Gas & Electric Corporation for a determination of the commission that certain property is necessary to the improvement and full development and utilization of petitioner's water-power site on the Genesee River in the city of Rochester, where the major part of the head and volume of the usable flow for power is now owned by the petitioner. This application, filed with the Public Service Commission a few weeks ago, had been held up pending the determination of the Court of Appeals in the Horton case, now made.

## Muscle Shoals Act in President's Hands

### "Pocket Veto" Expected at Washington—He Approves Resolution Forbidding Private Development at Gorge of Potomac Until Further Action by Congress

BY PAUL WOOTON

Washington Correspondent of the ELECTRICAL WORLD

CONGRESS adjourned on Tuesday afternoon, May 29, with the Muscle Shoals bill still unsigned. As it was stated at the White House that the President was waiting for certain reports on the bill, it is assumed that he did not want to sign or to veto the measure until he had had an opportunity to study these recommendations. The general expectation in Washington on Thursday, as this dispatch is filed, is that he will not sign the bill.

The conference report was adopted by 43 to 34 in the Senate and by 211 to 146 in the House. Obstruction and filibustering in the Senate, led by Senator McKellar of Tennesse, whose determined opposition was based on the inclusion in the final draft of the bill of the provision for government construction of a dam at Cove Creek in his state, brought an all-night session. Mr. McKellar, who termed the Cove Creek clause "incomprehensible" and thought it would unfairly deprive Tennessee of rights and revenue, finally gave up, exhausted, and the bill was passed at 11.50 a.m. after the Senators who had absented themselves from the night sitting reappeared.

In this connection question has been raised as to the effectiveness of the so-called "pocket veto" at the close of a session of Congress. Some argue that failure to sign a bill delivered to the President less than ten days before adjournment of any but the last session of a Congress automatically makes it a law. No ruling on this question has been handed down by the Supreme Court, but a case involving it is now going through the legal machinery. The prevailing opinion, however, is that by any reasonable interpretation of the constitutional provision a bill left unsigned under such conditions at the end of a session dies just as certainly as does one left unsigned at the final session of a Congress. It is generally accepted that the President is privileged to sign a bill after adjournment. A notable example of the exercise of this power was had in the signing of the water-power act by President Wilson in 1920.

#### RESOLUTION ON THE POTOMAC

Among the bills signed by the President at the Capitol just before adjournment was the joint resolution directing the Federal Power Commission to issue no permit to any private interest for the development of water power on the Potomac in the Washington area until further action by Congress after considering reports that will be made by the National Capital Park and Planning Commission and the Federal Power Commission as to the best utilization of the gorge of the Potomac for the public benefit.

The President also signed at the Capitol the resolution providing for the striking of a medal commemorative of the achievements of Thomas A. Edison "in illuminating the path of progress through the development and application of inventions that have revolutionized civilization in the last century." Passage of the resolution was stopped in the Senate for a time by objections of

Senator La Follette. When assured that, before reporting the resolution favorably, the banking and currency committee had investigated claims that Mr. Edison had been given credit for inventions really made by others, the Wisconsin Senator withdrew his objection.

## Boulder Dam Bill Gets Preferred Status

*Will Be "Unfinished Business" When Congress Reassembles in December—Hot Fight in Senate—Resolution for Further Engineering Investigation Becames Law*

After having provided the pyrotechnics which so frequently characterize the sessions of the Senate as adjournment approaches, the Boulder Dam bill failed of passage, but it remains the unfinished business of the Upper House. This agreement followed a filibuster precipitated by Senator Johnson's determination to reach a vote. In an all-night session starting on Monday the Arizona senators talked against the project, helped by other opponents. Excitement grew so high that the Senate finally went into executive session on Tuesday to calm down. Consideration of the measure—which was passed by the House on May 24 without a rollcall, a previous motion to recommit, made by Representative Douglas of Arizona, having been defeated by 219 to 139—will be resumed on the convening of the December session.

Senator Bruce of Maryland objected strenuously to the continuation of the Boulder Dam bill as the unfinished business. The Senator from California, he said, "did everything in his power to bring this bill—highly obnoxious to me and to other members of this body—to a vote. He failed and he should take the consequences of failure. I can see no reason why his bill should enjoy a privileged status at the beginning of the next session, only to be again an obstruction to other legislation, as it has been during the present session."

### Engineering Investigation Sure

Before the adjournment Congress passed and the President signed a joint resolution, introduced by Senator Pittman of Nevada, insuring a further engineering investigation of the project. This resolution reads as follows:

> The Secretary of the Interior is hereby authorized and directed to appoint a board of five eminent engineers and geologists, at least one of whom shall be an engineer officer of the army on the active or retired list, to examine the proposed site of the dam to be constructed under the provisions of H.R. 5773, Seventieth Congress, first session [the Swing-Johnson bill], and review the plans and estimates made therefor and to advise him prior to Dec. 1, 1928, as to matters affecting the safety, the economic and engineering feasibility and adequacy of the proposed structure and incidental works, the compensation of said board to be fixed by him for each respectively, but not to exceed $50 per day and necessary traveling expenses, including a per diem of not to exceed $6, in lieu of subsistence, for each member of the board so employed for the time employed and actually engaged upon such work. Provided further that the work of construction shall not be commenced until plans therefor are approved by said special board of engineers. No authority hereby conferred on the Secretary of the Interior shall be exercised without the President's sanction and approval. The expense herein authorized shall be paid out of the reclamation fund established by the act of June 17, 1902.

## "Platform of American Industry for 1928"

A full meeting of the Platform of American Industry Committee was held in New York City recently under the auspices of the National Association of Manufacturers, of which John E. Edgerton is president. This committee formulated a platform for 1928 for submission to the Republican and Democratic national conventions in the same way that former platforms were submitted in 1920 and 1924. The platform indorsed for this year contains planks on agriculture, the Federal Reserve system, flood control, foreign trade policies, government and business, immigration, international relations, judiciary, merchant marine, private employment relations, regulation of combinations, reorganization of government departments, tariff, taxation, transportation, and women in industry. M. S. Sloan, president Brooklyn Edison Company, was a member of the drafting committee. Following is the paragraph on "government and business":

> The function of our government is political—not economic. It was neither conceived nor fashioned to engage in competitive enterprise with its citizens, nor to administer the tasks of production and distribution, nor to substitute the judgment of its agents for that of responsible and experienced management in the direction of business operations. It is the servant and not the master of the citizen. It was established by him, under definitely limited authority, to protect and promote the pursuit of his chosen effort, assuring him security in the fruit of his endeavor, subject only to equal and impartial restraint essential to the maintenance of like opportunity and liberty for all.
>
> We urge more reliance upon private energy and character and less upon public law and appropriations. The interdependence and complexity of modern life make necessary new limitations upon individual liberty, but these are justifiable only as they are demonstrated to be necessary and practically effective to accomplish their purpose. Self-government is self-support. To discourage initiative and lessen self-reliance destroys the dynamic force of the individual. Our government must rely upon the support of the citizen; the citizen must learn not to lean upon the government.

## New York Activities Delved Into

### Empire State's Utility Information Committee's Practices in the Promotion of Good Public Relations Investigated, as Are North Central Bureau's

When the utility-industry investigation was resumed by the Federal Trade Commission on Monday, May 28, Fred W. Crone, director of the New York State Committee on Public Utility Information, took the stand and was examined on the public relations activities of that bureau. He testified that about $227,000 had been spent since 1922 for its purposes. Two booklets had been published purporting to state the attitude of the state's public utilities with respect to water-power development. One, entitled "Water Power in New York State," attained a circulation of 196,000 among newspapers, libraries, public officials, college professors, commercial and banking houses and civic organizations, Mr. Crone testified. The other, entitled "River Regulation in New York State," had a circulation of 40,000. These publications were frankly against power development by the state.

Pamphlets prepared by Mr. Crone and intended to present the case for privately owned utilities "in a matter-of-fact light" had been distributed to the number of 106,000 copies, 491 high schools being made the agencies for distribution. In a survey made by Mr. Crone for the educational committee of the National Electric Light Association, he described fourteen out of twenty-five books used in New York schools as, in his opinion, unfair to the utility companies. He favored liberal advertising by the companies in newspapers, but expressed indignation at the idea that the representatives of the industry designed in this way to insure the insertion of favorable reading matter.

C. H. B. Chapin, secretary of the Empire State Gas and Electric Association, gave testimony along similar lines. He said his association was in no way connected with the distribution of propaganda against the Boulder Dam project and declared that it had nothing to do with state legislation. Judge Healy asked Mr. Chapin if the purpose of publishing the pamphlets on state water power was to offset Governor Smith's theory of development of water-power resources. "That was partly the purpose," said Mr. Chapin.

On Tuesday John W. Lapham of Minneapolis, head of the North Central Public Utility Information Bureau, testified regarding the enlistment of the aid of University of Minnesota professors in rural electrification projects. A payment of $5,000 a year is made to the university. Payments of traveling expenses of college professors were also acknowledged. Mr. Lapham testified that his bureau spent from $15,000 to

$18,000 a year on its activities in Minnesota, North and South Dakota.

Telegrams subpœnaed from the files of the Postal Telegraph Company which were sent by Josiah T. Newcomb, counsel of the Joint Committee of National Utility Associations, to utility company heads and others interested in the committee's work contained nothing new or that invited suspicion of improper activities.

No session of the investigating body was held on Wednesday—Memorial Day. On Thursday morning Colorado public utilities men were to take the stand. There will be no hearings next week on account of the N.E.L.A. convention, which will be attended by persons who otherwise might be called as witnesses. It is expected that the hearings will be resumed the week of June 10.

## Operation at and Near Philadelphia Consolidated

Operations of the Philadelphia Electric Company, the Delaware County Electric Company and the Philadelphia Suburban-Counties Gas & Electric Company were to be consolidated June 1, President Taylor of the first-named company announced. The consolidation of operations does not constitute a merger nor does it entail any change in the financial status of the companies concerned. The purpose is to enable logical expansion of service in the Philadelphia metropolitan district and to give the communities served the advantages made possible through unified operation. In order to put the new plan into effect, the new territory has been divided into five major divisions as follows: Philadelphia and its various district offices; Delaware Division, headquarters at Chester; Main Line Division, headquarters at Ardmore; Schuylkill Division, headquarters at Norristown, and Eastern Division, headquarters at Jenkintown.

## New Jersey Public Service Rounds Quarter Century

Attainment of a quarter century of existence by the Public Service Corporation of New Jersey was to be celebrated on Friday evening, June 1, at the Robert Treat Hotel, Newark, by a banquet which was designed also to mark the completion of 25 years in service as head of the parent company and its subsidiaries by Thomas N. McCarter. Those who were to speak had not been announced as the ELECTRICAL WORLD went to press, but among the 600 guests expected were, in addition to the directors and officers of the companies, such prominent political, industrial and utility leaders as Senator Edwards and Governor Moore of New Jersey, E. T. Stotesbury, A. W. Thompson, O. D. Young, John B. Miller of Los Angeles and President J. F. Autenrieth of the New Jersey Board of Public Utility Commissioners.

## New Honor for Edison

*Gold Medal Awarded Him by Society of Arts and Sciences at Large Gathering Addressed by Public Utility Men and Educators*

IN RECOGNITION of his superservice to mankind, the Society of Arts and Sciences bestowed its gold medal for sciences upon Thomas A. Edison on Thursday, May 24. The presentation dinner was held in the Hotel Astor, New York City. Mr. Edison, who has not yet returned North from his Florida home, asked that his son, Charles Edison, might represent him, and the latter accepted the medal on behalf of his father and read a letter of appreciation from the great inventor. Men and women prominent in educational, industrial, public utility and other fields gathered for the dinner to the number of six or seven hundred, a few among them, in addition to the speakers named below, being President James R. Angell of Yale University, President S. W. Stratton of the Massachusetts Institute of Technology, Dr. John H. Finley, Dr. Willis R. Whitney, and diplomatists and consuls-general from many foreign countries.

*Souvenir plaque of Edison dinner*

In making the presentation, President Walter Russell of the Society of Arts and Sciences paid a rhetorical tribute to Edison as a man as well as an inventor, dwelling on modesty and unselfishness as traits that endeared him to the fellow men for whom he had accomplished so much.

Dr. Frank B. Jewett, vice-president American Telephone & Telegraph Company, spoke of Mr. Edison as a great engineer whose imagination and skill have correlated the fragments of science and research for the purposes and benefits of mankind. Dean William F. Russell of Teachers' College, Columbia University, made mention of the debt that education owed this inventor who had increased the wealth of a nation, thus providing the economic bases on which schools can be supported. Dr. John Campbell Merriam, president Carnegie Institution of Washington, in considering the value of Mr. Edison's work, said that the world as transformed by machinery and science may not in the abstract be a better one, but that it is a more comfortable one in which to live and that life in it is more effective and satisfactory. Dr. Howard McClenahan, secretary of the Franklin Institute, expressed the feeling that Mr. Edison marked the passing of the earlier type of inventor—that of the great individualist—who is being replaced by great corporations and associations. Arthur Williams, vice-president New York Edison Company, recounted some intimate reminiscences of the early days of the career of the man honored. Prof. Karl T. Compton of Princeton University eulogized the medalist as a scientist, scouting invidious whisperings that he is "only an inventor."

Entertainment features of the evening followed closely the spirit of the occasion. Thomas Wilfred's color organ and Leon Theremin's "ether music" were among the numbers.

## New York & Queens Company Reduces Rates

Officials of the New York & Queens Electric Light & Power Company, serving Queens Borough in Greater New York with electricity, announced on Thursday morning a further reduction in the maximum rate to its consumers from 8½ to 8 cents per kilowatt-hour. The new rate will go into effect on July 1. This reduction, Vice-President H. L. Snyder said, will mean an annual saving to customers of approximately $700,000 and constitutes the fourth in a series of reductions in the past three years.

## Power Companies Aid New England Growth

Nearly ninety power companies in New England have lately established industrial development departments and have assigned members of their organizations to carry forward the work of bringing industries into areas suited to their activities in the six Northeastern States. These departments are co-operating with the New England Council, local chambers of commerce, railroads and other organizations interested in promoting the growth of diversified industries in this territory. During the next few months the committee on industrial development of the power industry, which is co-operating with the council, will undertake a study of industrial surveys, their purposes and uses, and as a result it is expected that a standard form of industrial survey will be made available to electric service companies.

Another study is being made of the use and results of paid advertising by power companies throughout the country as a means of promoting industrial growth.

# Henry L. Doherty Sees "Nothing But Expansion"

A MESSAGE to the Electrical World from Henry L. Doherty, head of Henry L. Doherty & Company and the Cities Service Company, sent from Battle Creek, Mich., where he is convalescing from his recent illness, strikes a note of firm faith in the future growth of the industry. Mr. Doherty says:

*H. L. Doherty*

In my many years of experience in the central-station business I do not remember that there ever was a time when some one was not predicting that we had about reached the point of saturation for the use of electrical energy. In my earlier years, and especially when I was trying to induce all of the central stations to inaugurate intensive sales campaigns, I earned the reputation of being very visionary, because it was believed that my prophecies as to the amount of business we could develop were wildly optimistic. Since then I have lived to see all of the figures I had ever made look so small in comparison with actual results that the same people who once called me visionary would with these figures and actual results before them say that I was a piker. I know that we have not only not reached the saturation point for the use of electrical energy, but I know that we are not even approaching near to that point.

New uses for electrical energy keep springing up even faster than we can supply the need for the previously known uses. The investing public has been brought to the point where many of its members regard the securities of our electric supply companies as the most desirable form of investment, and I think we shall see more and more people turn to electrical securities and more and more of them regard them as the best possible type of investment. The wide distribution of our securities has been a most important factor in popularizing our companies, and this factor would alone justify our customer-ownership campaigns.

I am able to see nothing but expansion and still further expansion ahead of us. If you were to ask me what was the greatest asset the industry had I would tell you that I believe it is the trained men that conduct every branch of our business. I do not want to make any unpleasant comparisons, but if there is any industry that can rank with the electrical industry in this important particular, I don't know what it is.

## Purchases and Mergers

The Connecticut Power Company of New London will take over control of the Union Electric Light & Power Company of Unionville, Conn., through an exchange of stock. The territories served by the two companies are adjacent. The Union Electric Light & Power Company serves Avon, Canton, Burlington, New Hartford and Farmington, and its properties are valued at $1,750,000.

Petition for the purchase of the Genesee Valley Power Company of Fillmore, N. Y., has been filed with the New York State Public Service Commission by the Rochester Gas & Electric Corporation.

The transfer to the Annapolis & Chesapeake Bay Power Company of the Herald Harbor Lighting & Power Company and of the Severna Electric Company is announced. The purchasing company is a subsidiary to the Consolidated Gas, Electric Light & Power Company of Baltimore. The companies acquired are in Anne Arundel County. Approximately $10,000 was paid for the Severna Park company and about $4,650 for the Herald Harbor company.

Application to the Dauphin County Court by the Hummelstown (Pa.) Water & Power Company for permission to surrender its charter has been made. This is preliminary to a separation of the two departments of the company and the merging of the electric end with the Pennsylvania Power & Light Company.

The municipal electric lighting plant at Dahlgren, Ill., has been purchased by the Central Illinois Public Service Company, which will build a transmission line there.

The Union Power Company of Drumheller, Alberta, Canada, a subsidiary of the International Utilities Corporation, has acquired at a cost of $80,000 the plant at Three Hills which supplies electric light to Three Hills and Trochu.

The Islands Edison Company (formerly the Manila Gas Company) is about to acquire the entire capital stock of the Compañia Electrica de Santo Domingo, which furnishes light and power to the cities of Santo Domingo and San Pedro de Macoris in the Dominican Republic.

## Cooper Assails New York for Hydro-Electric Failure

Thirty millions of dollars annually is the cost to New York State of its failure to develop potential water powers, Colonel Hugh L. Cooper, engineer and authority on hydro-electric development, asserted in an address delivered at the annual meeting of Associated Industries of New York State at Syracuse on May 25.

Mr. Cooper, who designed and now is engaged in constructing an eight-million-dollar hydro-electric plant on the Dneiper River, in the Ukraine, for the Soviet government, criticised the business men of the state "for their indifference and their failure" to develop the three million available horsepower which he said is now being wasted. Such development, he declared, would cost $570,000,000, "but such an investment would support a new and existing industrial development of approximately three and a half billions of dollars in New York State. "Within the last three years," said Mr. Cooper, "new industries that would have used more than 400,000 hp. have knocked at your doors for cheap energy and have been denied."

Mr. Cooper characterized inability to decide whether to develop the state's water powers by government or by private agencies as "a miserable admission of lack of intelligence." He then reviewed the history of governmental development and control of water power, citing specific examples to prove that private development and control provided cheaper power. "Because of the procrastination in the State of New York that has prevailed in the last ten years," he said, "the St. Lawrence is in actual danger at this time of being developed in a manner and according to plans that are far from being in the interest of the people of the state."

## Thousands View Illumination of Great Shoshone Falls

A crowd of automobilists and others estimated at ten thousand persons witnessed on May 24 the illumination of the Great Shoshone Falls, on the Snake River in southern Idaho, by 30 floodlamps with a total rating of 25,000,000 cp. The lighting system was installed on a shelf in the canyon. The spectacle lasted from 9 o'clock until midnight, with alternate flashes of rainbow hues and colored squares upon the foaming water and the lava rock walls of the canyon.

W. R. Putnam, Boise, vice-president and general manager of the Idaho Power Company, told of his company's plans to make Shoshone Falls as great a natural attraction for the West as Niagara is for the East. The lighting is to continue every night from dusk until midnight. the colored illumination being used on special occasions.

# Denver A.I.E.E. Convention Promises Well

*Well-Varied Program of Technical Papers and Discussions—One Day to Be Spent in Exploring Mountain Parks—Yellowstone Trip*

SURGE-VOLTAGE investigations on transmission lines, control and protection of feeders for electrified railways, alternating-current elevator motors, electric welding of pipe lines, telephony, transmission experiences, extinction of alternating-current arcs, high-frequency supervisory control and geophysical prospecting are the main topics that will be treated in the papers and discussions at the summer convention of the American Institute of Electrical Engineers at Denver. This convention is to be held from June 25 to June 29, and headquarters will be at the Cosmopolitan Hotel.

The annual dinner-dance will be held on Wednesday evening. Attractive journeys arranged, in addition to the customary sport and recreation, include an all-day trip through Denver's mountain parks and the Bear Creek Canyon and a tour of Yellowstone Park. The former will occupy the morning and afternoon of Thursday, June 28, and be followed by a theater party in the evening. The latter will start immediately after the convention closes. Tuesday and Friday afternoons will be devoted to golf and tennis tournaments. The tentative technical program follows:

MONDAY, JUNE 25

Registration, section delegates' and branch delegates' meetings.

TUESDAY, JUNE 26

*Morning.*—President's address; session A, Surge-Voltage Investigations: "Surge-Voltage Investigation on Transmission Lines," W. W. Lewis, General Electric Company; "Lightning Investigations on New England Power Company's System," E. W. Dillard, New England Power Company; "Surge-Voltage Investigation on 140-Kv. System of Consumers Power Company," J. G. Hemstreet and J. R. Eaton, Consumers Power Company; "Surge-Voltage Investigation on 132-Kv. Transmission Lines of American Gas & Electric Company," Philip Sporn, American Gas & Electric Company; "Surge-Voltage Investigation on 220-Kv. System of Pennsylvania Power & Light Company," N. N. Smeloff, Pennsylvania Power & Light Company.

*Evening.*—Lecture, "Geophysical Methods of Prospecting," Dr. C. A. Heiland, Colorado School of Mines.

WEDNESDAY, JUNE 27

*Morning.*—Sessions B and C, technical committee reports (two simultaneous sessions).

*Afternoon.*—Session D, Electrified Railways, Feeder Control: "High-Speed Circuit Breakers," J. W. McNairy, General Electric Company; "High-Speed Circuit Breakers for Railway Electrification," H. M. Wilcox, Westinghouse Electric & Manufacturing Company; "Operating Experience with High-Speed Circuit Breakers," B. F. Bardo, New York, New Haven & Hartford Railroad; "Arrangement of Feeders and Equipment for Electrified Railways," R. B. Morton, of Gibbs & Hill; "Protection of Electric Locomotives and Cars to Operate with High-Speed Circuit Breakers," E. H. Brown, Pennsylvania Railroad; "High-Speed Circuit Breaker in Railway Service," W. P. Monroe and R. M. Allen, Illinois Central Railroad.

FRIDAY, JUNE 29

*Morning.*—Sessions E and F (two simultaneous sessions). Session E: "A Formula for Minimum Horizontal Spacing of Transmission-Line Conductors," P. H. Thomas, consulting engineer; "Transmission Experience of the Public Service Company of Colorado," M. S. Coover, University of Colorado, and W. D. Hardaway, Public Service Company of Colorado; "Alternating-Current Elevator Motors of the Squirrel-Cage Type," E. E. Dreese, Lincoln Electric Company; "Electric Welding of Pipe Lines," J. D. Wright, General Electric Company. Session F: "Utilization of Lodge-Pole Pine as Pole Timber," R. W. Lindsay, Mountain States Telephone & Telegraph Company; "Carrier Systems on Long-Distance Telephone Lines," H. A. Affel and C. S. Demarest, American Telephone & Telegraph Company, and C. W. Green, Bell Telephone Laboratories; "Superimposed High-Frequency Currents for Circuit-Breaker Control," L. R. Ludwig, Westinghouse Electric & Manufacturing Company; "Extinction of an Alternating-Current Arc," Joseph Slepian, Westinghouse Electric & Manufacturing Company.

# American Papers for Tokyo Congress Discussed

Adequate presentation of America's engineering and industrial story at the sessions of the World Engineering Congress to be held in Tokyo next year was discussed at a meeting of the executive committee of the American general committee for the congress held in New York on May 18. Hospitality to be extended in the United States to European delegates in their movement from the Atlantic to the Pacific on the way to the Tokyo congress was another subject which came up at the meeting. The entertainment committee reported that local engineering societies already have volunteered their services as hosts to the delegates from Europe.

The importance of careful selection of papers which will collectively reflect the status and tendencies of each of the major branches of engineering in this country, rather than cover unrelated miscellaneous topics, was stressed in the report of the technical program committee, headed by Prof. Dugald C. Jackson, who announced the following as members, with himself, of the technical program committee: Allen Hazen, vice-chairman; H. Foster Bain, Alex Dow, W. F. Durand, J. R. Freeman, Bancroft Gherardi, George W. Fuller, F. L. Hutchinson, Major General Edgar Jadwin, Dean Dexter S. Kimball of Cornell, A. D. Little, Fred R. Low, O. C. Merrill, Prof. Michael I. Pupin, Calvin W. Rice, George T. Seabury, George Otis Smith and W. E. Wickenden.

# Stratton Doubts Wisdom of Exporting Maine Power

Remarks made by President S. W. Stratton of the Massachusetts Institute of Technology at an industrial conference held recently in Maine have encouraged the opponents of the exportation of surplus hydro-electric energy. As reported, Dr. Stratton said: "The restriction that confines the use of water power to Maine may be a blessing to the state in the long run. Wherever water power has been long developed it has proved advantageous to bring manufacturers close to the power." He went on to cite aluminum manufacture at Niagara Falls as a parallel instance and drew the conclusion that "these new water-power plants of Maine will in time become veritable gold mines."

An Augusta report says that as a result of President Stratton's remarks it is believed there that the chances that the Legislature will lift the power ban are not so favorable as they would have been if his views had coincided with those of many other engineers. Governor Ralph Brewster, who is seeking Senator Frederick Hale's seat in the United States Senate, has during his two terms in office opposed strongly the lifting of the ban against the exportation of power. William Tudor Gardiner, who will possibly be the Republican candidate for Governor, believes that the matter should be settled by a referendum vote. He is said to be more favorable to the power interests as far as exportation goes than any of the other candidates.

Although the platform of the state Democratic party declares for exportation of power, conditioned with certain safeguards for the home consumers, Edward C. Moran, Jr., who will be the Democratic candidate for Governor, declared in Portland that he does not favor exportation of surplus hydro-electric power and is opposed to any legislation which would permit such traffic.

# Progress Toward International Technical Co-ordination

A recent notification from the central office in London of the International Electrotechnical Commission concerning the co-ordination of international technical meetings, in accordance with the movement initiated in Italy last September, says:

In January of this year a first meeting of the unofficial "comité d'entente," as it was suggested it should be called, was held in London at the offices of the I.E.C., when representatives were present from the International Illumination Commission, World Power Conference, International Consultative Committee on Long-Distance Telephony, International Union of Producers and Distributors of Electrical Energy, International Standards Association (in process of formation) and the International Electrotechnical Commission. Prof. Clarence Feldmann of Holland, the new president of the I.E.C., was in the chair, and an interesting exchange of information took place regarding dates of future meetings and in one or two cases on the preliminary programs. It was felt that if information of such a character regarding dates and programs could be exchanged at infrequent intervals, say once annually, it would be bound gradually to lead to most helpful co-operation and be of advantage to the delegates attending the many international meetings as well as probably to enhance the value and usefulness of the meetings themselves.

The question of co-operation between international organizations by joint international committees as well as by observers was also touched upon. Finally it was decided to keep the unofficial committee in being, with the I.E.C. as convener, and to call another meeting a year hence by which time the various organizations represented would have had time to give their official decision—which in most cases, it is anticipated, will be favorable—regarding the permanent establishment of such a committee. It is also hoped that other international organizations in the technical field will be interested in this co-operative idea, which, while leaving each organization entirely free, yet provides a kind of clearing house through which information may be exchanged and administrative matters discussed in a free and friendly manner.

## Radio Corporation Accused by Trade Commission

Charges that the Radio Corporation of America has violated the laws against "unlawful restraints and monopolies" were made by the Federal Trade Commission on May 23, and July 23 was fixed as the date for a hearing at Washington. The charges are directed against a "license agreement" made by the Radio Corporation with about twenty-five of the principal manufacturers of radio receiving sets, representing approximately 95 per cent of production, under which agreement a three-element vacuum tube essential to the sets must be purchased from the Radio Corporation, no opportunity for competition by other tube manufacturers being allowed. These tubes were formerly protected by General Electric, Westinghouse and American Telephone & Telegraph patents, but since the expiration of these patents in 1924 and 1925 their manufacture has been open to any one. The Radio Corporation is the exclusive distributor for receiving sets and vacuum tubes made by the General Electric and Westinghouse companies.

## Upper Rio Grande Exploration Shows Possibilities

Co-operating with and accompanying several members of the joint commission of water conservation and power possibilities of the Rio Grande, the Texas State Board of Water Engineers, with ten engineers and other irrigation and hydro-electric experts, has just completed a tour of the international boundary stream along its remote upper course. At points in the Big Bend region, 80 to 100 miles from the nearest railroad point, they selected sites for three dams which would impound a total of approximately 10,000,000 acre-feet of water and provide energy for generating an enormous supply of hydroelectric power.

C. S. Clark, chairman of the Board of Water Engineers, stated that by constructing a dam 250 ft. high across Boquillas Canyon 4,000,000 acre-feet of water would be impounded. Similar dams in Mariscal Canyon and Santa Helena Canyon would impound an additional 6,000,000 acre-feet of water, Mr. Clark said. The constructing of these dams would insure a permanent water supply for irrigating vast areas of rich lands on the American and Mexican sides of the Rio Grande and would enable the generation of electric power for supplying towns and industries for three hundred miles around. As a result of the investigations and surveys, a report favorable to the carrying out of the projects will be made to the United States and Mexican governments.

# Briefer News

ANOTHER CALIFORNIA UTILITY TO REDUCE RATES—The Coast Counties Gas & Electric Company, with headquarters at Santa Cruz, Calif., has asked the California Railroad Commission for authority to reduce its rates for electric service and place them on a parity with rates of the Pacific Gas & Electric and Great Western Power companies in the same general territory.

PHILADELPHIA ALSO PLANS AN INDUSTRIAL MUSEUM.—The Franklin Institute has $1,900,000 available toward the fund needed for building a great museum of industry and physical science on the Philadelphia Parkway and is "confidently expecting to build it," Dr. Howard McClenahan, secretary of the institute, told the Philadelphia Engineers' Club last week. No such museum as yet exists in the United States, Dr. McClenahan said, but New York, Chicago and Detroit have funds available and are expecting to build such museums in the near future. He described the museums of this type in London, Paris, Munich and Vienna.

## *Coming Meetings*

**[A complete directory of electrical associations, with their secretaries, is published in the first issue of every volume. For latest list see ELECTRICAL WORLD for Jan. 7, page 80.]**

**National Electric Light Association—Atlantic City, June 4-8. P. S. Clapp, 420 Lexington Ave., New York.**

**American Association of Engineers—Hotel Hussman, El Paso, Tex., June 4-6. M. E. McIver, 63 E. Adams St., Chicago.**

**National Electrical Manufacturers' Association—Radio Division, Chicago, June 4-7.**

**Electrical Supply Jobbers' Association—The Homestead, Hot Springs, Va., June 5-8. E. Donald Tolles, 165 Broadway, New York.**

**National Electrical Manufacturers' Association—The Homestead, Hot Springs, Va., June 11-15. S. N. Clarkson, 420 Lexington Ave., New York.**

**Artistic Lighting Equipment Association—Hotel Sherman, Chicago, June 11-16. G. P. Rogers, 420 Lexington Ave., New York.**

**Pacific Coast Division, N.E.L.A. — Hotel Huntington, Pasadena, Cal., June 12-15. S. H. Taylor, 447 Sutter St., San Francisco.**

**Georgia Electrical Association—Savannah, June 14 and 15. J. J. McDonough, Georgia Power Co., Dublin, Ga.**

**Northwest Division, N.E.L.A.—Portland, Ore., June 19-22. B. Snow, 1208 Spalding Bldg., Portland, Ore.**

**Canadian Electrical Association—SS. "Richelieu" from Montreal to Saguenay and return, June 20-23. H. M. Lyster, 712 Power Bldg., Montreal.**

**American Institute of Electrical Engineers—Cosmopolitan Hotel, Denver, June 25-29. F. L. Hutchinson, 33 West 39th St., New York.**

**Association of Iron and Steel Electrical Engineers—Hotel Stevens, Chicago, June 25-28. J. F. Kelly, Empire Bldg., Pittsburgh.**

**American Society for Testing Materials — Chalfonte-Haddon Hall, Atlantic City, N. J., June 25-29. C. L. Warwick, 1315 Spruce Street, Philadelphia.**

**Public Utilities Advertising Association—Detroit, July 8-12. T. P. Pfeiffer, Byllesby Engineering & Management Corp., Chicago.**

**East Central Division, N.E.L.A.—Cedar Point, Ohio, July 10-13. D. L. Gaskill, Greenville, Ohio.**

**National Electric Credit Association—Boston, July 16 and 17. F. P. Vose, 1008 Marquette Bldg., Chicago.**

**Wisconsin Utilities Association, Electric Section—Appleton, Wis., July 26 and 27. J. N. Cadby, 432 Broadway, Milwaukee.**

ROCHESTER (N. Y.) GAS & ELECTRIC'S TWENTY-SEVENTH SUBSTATION. — Land for a new substation, the twenty-seventh in the Rochester Gas & Electric Corporation's chain within the city limits, has been acquired in the southeast section of Rochester. This station will be completed in another year. It is designed to provide for a rapidly growing residential section.

NEW UNIT FOR DUBUQUE, IOWA.—Extensions and improvements are being made at the Dubuque plant of the Interstate Power Company which will increase its capacity to more than three times that of three years ago. The work includes the installation of a 15,000-kw. generating unit with its accessories and of a larger water-pumping system and the building of additional transmission lines. The extensions are expected to be completed in a few months.

GAS-ELECTRIC CARS TO REPLACE STEAM LOCOMOTIVES ON A MOBILE & OHIO DIVISION.—Plans for the replacement of steam locomotives by gas-electric-operated trains in the passenger service on its 181-mile Montgomery-Artesia division have been announced by the Mobile & Ohio Railroad. The new trains consist of two coaches, one a combination car and the other a standard passenger coach of the type built for the gas-electric railroad service. Steam trains will continue to be operated for freight service.

NEW HYDRO PLANT FOR PHILIPPINES SUGGESTED.—A trip over the southern islands in the Philippines by Vice-President L. P. Hammond of the Electric Bond & Share Company, New York, to determine economic possibilities there is understood to have led to a report that the Agos Falls, on the Agos River in Lanao, Mindinao, could be utilized to supply all the power needed in that territory for a long time to come. The falls have a drop of 2,300 ft. and are capable of generating about 32,000 hp., but a market is lacking.

RICHMOND TO TAKE OVER WATER-POWER RIGHTS ON THE CHESAPEAKE & OHIO CANAL.—An agreement with the Virginia Electric & Power Company whereby the city of Richmond and the company can exchange power for five years on a new price basis has been reached in connection with negotiations by the city for water rights on the Chesapeake & Ohio Canal. The proposed contract provides that the city may take over all the water-power rights of the power company on the Haxall Canal, provides for a power exchange contract with a five-year term and new exchange prices and clears the way for the city's use of 88 cu.ft. of canal water per second for power as well as for water supply. Agreements whereby the city will take over the Atlantic Coast Line Railway's water rights on the Chesapeake & Ohio Canal have also been reached. Both these agreements must be confirmed by the City Council.

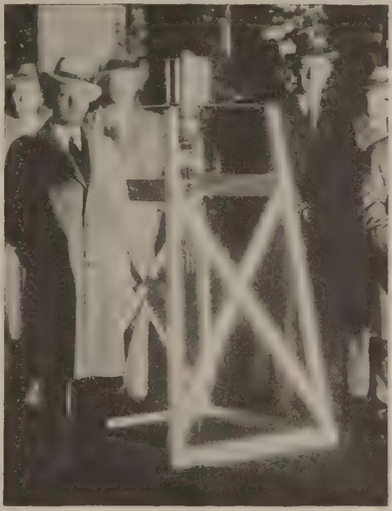
Mouth-of-Mine Plant in Saskatchewan. — Work will commence soon on the first unit of the Montreal Engineering Company's plant to generate electrical energy at the mouth of the coal mines in the Canadian province of Saskatchewan. The plant as designed will eventually cost $750,000, but for the present a third of that sum will be spent on building, machinery and equipment. The plant will be located between Bienfait and Estevan, and the company will distribute power wherever economic distribution will permit.

Plan for Government Hydraulic Laboratory Loses.—Not only did the rivers and harbors committee of the House of Representatives refuse to approve the bill passed by the Senate authorizing the establishment of a hydraulic laboratory in the Bureau of Standards, but it also refused to approve the bill with an amendment which would permit the Corps of Engineers to establish its own hydraulic laboratories at river sites. As there were only four votes in the committee for the bill as amended, it is apparent that no further progress can be made with it unless a change of reference is obtained next session.

Empire District Electric Company Prepares to Build Table Rock Dam. —The Empire District Electric Company of Joplin, Mo., has filed an application with the Missouri Public Service Commission for a certificate of convenience and necessity to construct and operate its long-projected hydro-electric power plant and dam at Table Rock in Taney County on the White River. The dam will be 1,924 ft. long and 197 ft. above bedrock and will be able to furnish power for four 37,000-kw. generators and have an ultimate annual production energy of 410,000,000 kw.-hr. Cost of the project will be $16,700,000 when it is finally completed, according to estimates. The company has a preliminary permit from the Federal Power Commission and has applied for the final license.

Ohio Utilities to Provide Work for Ten Thousand Men. — Public utility companies in Ohio will provide employment for approximately ten thousand men on new construction projects in 1928, according to announcement by the Ohio Committee on Public Utility Information. In addition to very large telephone undertakings, the Cleveland Illuminating Company will employ 1,100 men on the erection of two 132-kv. power lines, at an estimated cost of $11,500,000; the Dayton Power & Light Company will need 450 men in completing construction work estimated to cost $2,500,000, and the Union Gas & Electric Company will use 600 men in work to cost $7,800,000. Other light and power utilities planning expenditures are: Toledo Edison Company, $2,250,000; Ohio Public Service Company, $2,000,000; Ohio Edison Company, $270,575; Columbus, Delaware & Marion Electric Company, $235,000, and Southern Ohio Public Service Company, $260,000.

Nela Park Celebrates Manufacture of 50,000-Watt Lamp.—The first public showing of the new 50,000-watt incandescent lamp constructed by engineers of the General Electric Company was held at Nela Park in Cleveland a week or two ago, and many citizens gathered to see it. A 30,000-watt lamp furnished the necessary light for the photograph, which was taken outdoors during a blinding rain. The new lamp is of the gas-filled tungsten-filament type, with a tall chimney-like extension of the bulb equipped with radiating disks.



Canadian Supreme Court Defers Argument on Provincial Power Rights. — According to a decision handed down by the Chief Justice of the Supreme Court of Canada, the argument between the Dominion government and the provinces on questions respecting power and property rights on navigable streams will not be heard until September. The issue was to have been joined on June 28. The seven questions submitted to the Supreme Court by the Dominion government were criticised by Eugene Lafleur, counsel for the province of Quebec, when he appeared before the court on May 21 to urge the postponement of the hearing. The questions were so general and so abstract, he said, that it was imposible to forecast what the real issues were going to be. They should be in some concrete form, but as they stood they could not be intelligently answered by any court. Mr. Lafleur said he had the support of British Columbia and Manitoba in his contention.

Eel River Hydro Site Sought.—An application for permission to divert 137,385 acre-feet and 189 sec.-ft. of water from the North Fork of the Eel River near Mina,. Mendocino County, for power and domestic purposes, was filed with the California State Division of Water Rights on May 16 by Frederick C. Rockwell of Carmel, Calif. The project will produce 24,431 hp. and will cost approximately $1,500,000, he says. Construction is to begin six months after the permit is issued, and the project will be completed within three years.

Movement for State Ownership of Hydro Resources in Oregon Gains No Momentum.—No further actions have been taken by the Oregon Berry Growers' Association in connection with a resolution adopted last March which had for its purpose the launching of a campaign in behalf of state ownership and operation of hydro-electric utilities. This association proposed to circulate an initiative petition for public ownership and the development of natural resources by the state, but no such measure will appear on the May ballot, nor are there any developments to indicate that an amendment of the kind will be submitted to the electorate next November despite the organization's March resolution.

Shawinigan Company Gets St. Maurice Rapids Sites.—At a public auction conducted by the Quebec government on May 23 the Shawinigan Water & Power Company, as predicted last week, obtained the rights of developing a series of rapids on the St. Maurice River, which it has been estimated will mean an additional possible supply of power for that company reaching more than 500,000 hp. Shawinigan was the only bidder, and its bid of $5 over the upset price of $25,000 resulted in the company obtaining the lease. Preliminary investigation by the Quebec Streams Commission has shown that there are three principal sites for the construction of dams—Blanc Rapids, 172,000 hp.; Allard Rapids, 50,000 hp.; Secours Rapids, 85,000 hp. The company must start construction not later than July 1, 1930, and is also under obligation to have 100,000 hp. developed by July, 1933, expending in the undertaking at least $10,000,000.

Aylesworth Sees Bright Future for Radio.—Progress and possibilities of future development of radio broadcasting, radio and the electrical industry were described and outlined by M. H. Aylesworth, president of the National Broadcasting Company, in an address before the seventh quarterly luncheon of the Electric Association at the Palmer House, Chicago, May 24, at which more than six hundred representatives of the various divisions of the electrical industry were present. There are twelve million radio sets in the United States, two million of which, said Mr. Aylesworth, are small crystal sets and useful only for local reception. Several million sets will soon be replaced with modern equipment. He declared that the electrical industry has in radio an opportunity to render an outstanding public service in placing in the homes of all of the American people an indispensable equipment within the reach of rich and poor alike.

---

West Texas Service Still Expanding.—A new 8,500-hp. gas-burning generating unit at San Angelo, Tex., has begun serving customers of the West Texas Utilities Company. The distribution system at San Angelo was changed over from 2,300 volts to 4,150 volts, increasing the capacity of the system threefold. This change was made necessary by the phenomenal growth of San Angelo as a result of oil development. The new unit will supply all the needs of drilling and producing companies, refineries and pipe lines for electric power. It is the second to be built at San Angelo within the past year.

---

Utility Company and Indiana Tax Commission $7,300,000 Apart on Valuation. — For the Indianapolis Power & Light Company a tax valuation of $24,592,530 has been fixed for 1928, by action of the Indiana Board of Tax Commissioners, or an increase of $984,930 above the valuation for 1927. Harley L. Clarke, chairman of the company's board, a few days before had asked the commissioners for a reduction of $6,400,000. An opportunity to appeal from the board's appraisement will occur. An increase of $4,033,970 over the 1927 taxation valuation of the gas and electric properties of the Interstate Public Service Company of Indianapolis has also been made, bringing the total assessment of the company to about $25,000,000.

---

Iowa Hydro-Electric Projects.—The Cedar River water-power plant of the Iowa Public Service Company at Charles City, Iowa, will be rebuilt and improvements made at a cost of $100,000, according to Don Sterns, president. Contracts are to be let this month and the work completed by Nov. 1. The expansion of the Charles City power unit is designed to make commercial consumers in the territory independent of the Waterloo high-tension line.——The Central States Electric Company, which will complete a power dam at Iowa Falls, Iowa, within the next three months and has a petition before the Iowa Railroad Commission for authority to build a hydro-electric plant near Dolliver Park, Fort Dodge, Iowa, is contemplating an extensive power distribution program in the industrial region about Fort Dodge, its officers say. As a first step in this program petition has been filed with the state commission for authority to construct transmission lines in the Fort Dodge area to connect, eventually, with the proposed Dolliver Park dam.

# Commission Rulings

Allocation of Customer Costs. — In adjudicating proposed rate changes for the St. Joseph Gas Company, the Missouri Public Service Commission held that a rate structure theory claiming to give consideration to the rates charged the large consumers in order to increase sales and then proceeding to justify a proposed increase to 57 per cent of the small consumers by the use of an allocation of costs made upon the theory that all consumers may be taken as one class, the smaller class, is inconsistent and unfair.

---

Leased Property Not a Proper Item for Inclusion in Rate-Fixing Valuation.—Leased property, the Oregon Public Service Commission holds, is not a subject for consideration in the determination of a valuation of an electric utility for rate-making purposes. This decision was rendered in connection with the investigation of the valuation of properties owned by the People's West Coast Hydro-Electric Corporation, and the commission says: "The utility claims that the land which is leased, including the right to use water . . . and land upon which is located the substation and general office, . . . should be valued upon the same basis as property owned. The leases are for a limited term and the titles are held by others than the operating company. The lessee pays a rental which is included in operating expenses in accordance with the 'uniform classification of accounts' prescribed by this commission."

---

Arizona Corporation Commission Takes Jurisdiction Over Hydro-Electric Corporations.—Declaring that "the bestowing of legal rights and privileges and franchises authorizing the operation by public service corporations of natural water powers situate within the state, by means of certificates of public convenience and necessity, which may not be obtained elsewhere or otherwise, is the only manner in which the commission, in the exercise of its full powers to safeguard the rights of the state and fully protect its people, may impose the restrictions and limitations contemplated by the state constitution and the pursuant statute," the Arizona Corporation Commission has issued an order requiring all corporations engaged in hydro-electric development to obtain a certificate of convenience and necessity before engaging in such activity within the State of Arizona and assuming full jurisdiction, subject only to the limited sovereign powers of the federal government.

---

Rights and Obligations of Franchise Cannot Be Separated.—The Wisconsin Railroad Commission, rehearing a case in which the obligation of the Eagle River Light and Water Commission to give electric service to the town of Cloverland was concerned, because of new evidence brought out at an action in the County Court to set aside its decision, this evidence conflicting with the original evidence before the commission, reaffirmed its first decision, saying: "The franchise granted by the town of Cloverland to the village of Eagle River clearly gives the village of Eagle River an exclusive permit to operate in that town and includes the indeterminate permit defined by the statutes and with it the obligation to serve the public in that town. As stated in our former decision: 'The public utility cannot accept only such parts of the franchise as convey rights without assuming the obligations imposed by other parts of the same instrument. . . . It is neither equitable nor was it within the contemplation of the parties to the franchise that the grantee might segregate its parts and exercise rights under only a portion of it. By such exercise the utility must be deemed to have accepted the entire franchise with its burdens as well as its benefits.'"

# Recent Court Decisions

Company Holding City Franchise Cannot Refuse Service to Outlying Customer on Ground of Expense.—Confirming the trial court in Brown vs. Arkansas-Missouri Power Company, the Supreme Court of Arkansas has decreed that damages were properly awarded to the plaintiff because of the refusal of the company to serve him with electricity on the ground that the remote situation of his filling station would make doing so too expensive. The building in question was in the city of Pocahontas, south of the Black River, the improvements in the city being virtually all north of the river and a mile distant. The court held that the franchise accepted by the company made it compulsory to serve the applicant, regardless of loss, and the fact that since the judgment was rendered the territory in question had been detached from the city by the alteration of the latter's boundaries did not nullify the obligation assumed under former conditions so as to invalidate the award of damages, whatever the determination as to an existing obligation to serve—on which the court did not pass—might be. (4 S. W. [2d] 15.)*

---

Contributory Negligence of Children a Question for Jury.—Affirming judgment for the defendant in Wallace vs. Great Western Power Company, a damage suit brought because of the death of a twelve-year-old boy who climbed 33 ft. on an electric tower and received a fatal shock from high-voltage wires, the Supreme Court of California said that the question of contributory negligence is generally one of fact for the jury and that this principle applies in the case of children. None the less, the appellate court refused to upset the granting by the trial court of a motion for nonsuit, saying: "Assuming the defendant herein to have been guilty of negligence in the maintenance of this electric tower in an open and unguarded state within the limits or vicinity of a populous city [Oakland] and without the presence of signs or devices which would give warning to persons who might be tempted to play upon or ascend the tower, the trial court was still in a position, upon motion for nonsuit, to determine from all of the circumstances of the case whether the deceased boy, though a minor, was sufficiently intelligent and sufficiently familiar with the dangers incident to contact with high-power electric lines that his action in ascending this tower by the difficult means of ascent afforded, and to the height and place of danger to which he did thus succeed in climbing, was to be held negligence as a matter of law." (266 Pac. 281.)

# News About Men of the Industry

## *F. B. Lewis Elected to Vice-Presidency*

Fred B. Lewis, assistant general manager of the Southern California Edison Company, has been honored with the title of vice-president and in that capacity will assume greater responsibilities. In his new office he is to be vice-president and assistant general manager in charge of operation.

*F. B. Lewis*

Having joined the Edison company in 1905, following the completion of his engineering studies, Mr. Lewis has made steady progress from the position of meter reader to his present executive position.

During the 1924 power shortage Mr. Lewis, as chairman of the power committee, composed of representatives of all the power companies in the State of California, was very active in bringing about the interconnection of the physical systems of the electric utilities in California. One of his outstanding achievements during the four years in which he has been assistant general manager has been the inauguration of a system of budgets for operation of all departments.

During the nineteen years in which Mr. Lewis was associated with the Edison company, before being made assistant general manager, he had built up a background of steady and reliable performance. His first service with the Edison company was in the capacity of meter tester, which position he took after being graduated from Rose Polytechnic Institute at Terre Haute, Ind. He was advanced to the position of engineer of underground distribution, superintendent of the Los Angeles district, manager of operation and in 1924 to assistant general manager.

Joseph Insull, who has been assistant to the manager of the Pittsfield works of the General Electric Company since 1903, has just retired from active service at the age of 70. Mr. Insull has been connected with the General Electric organization for 41 years, starting in Schenectady. Later he became treasurer and manager of the General Incandescent Lamp Company in Cleveland and subsequently was named production manager of the General Incandescent Arc Light Company. Mr. Insull is a native of London, England. A gold watch was presented to him on his last day at the office by his associates.

James P. McKearin of the United Electric Light Company, Springfield, has been elected president of the Engineering Society of Western Massachusetts.

Dr. Vannevar Bush of the Massachusetts Institute of Technology was made the recipient of the Louis Edward Levy Medal by the Franklin Institute for two papers on electrical power transmission contributed to the Institute's journal.

Dr. Michael I. Pupin, professor of electromechanics at Columbia University and past-president of the American Institute of Electrical Engineers, has been made the recipient of the Washington award for 1928. This annual prize was founded in 1917 by John W. Alvord, consulting engineer of Chicago, for presentation to engineers who have rendered pre-eminent service in promoting the public welfare.

## *H. M. Sawyer Elected to New Executive Position*

H. M. Sawyer, general contract agent of the American Gas & Electric Company, has been elected vice-president. Mr. Sawyer was graduated from Cornell University in 1911, following which connection he joined the Scranton Electric Company as junior power engineer. In 1912 he went to Wheeling as power engineer for the Wheeling Electric Company and in 1920 he removed to New York as assistant general contract agent, being made general contract agent in 1924.

*H. M. Sawyer*

## *J. A. Longley Assumes New Duties in Tennessee*

James A. Longley, for the past several years manager of the production and transmission department of the Tennessee Electric Power Company, has been appointed assistant to the general manager of that company and assistant to the president of the Nashville Railway & Light Company. Mr. Longley is a native of Massachusetts and received his engineering education at Massachusetts Institute of Technology. His first connection with the electrical industry was in 1910 when he went to Portland, Ore., on power plant construction work for the Portland Railway, Light & Power Company. In 1913 he removed to Columbus, Ohio, just after the Dayton flood to work on location and construction of a power plant in that city, later transferring his interests to Nashville on the construction of the Nashville steam plant.

*J. A. Longley*

In October, 1914, he was transferred to Chattanooga as assistant general superintendent of the Tennessee Power Company and since that time he has been connected with the local utility interests with the exception of a year spent with the Arkansas River Oil & Gas Company in Kansas and Oklahoma. As manager of the production and transmission department of the Tennessee Electric Power Company Mr. Longley has been responsible for the operation of all power plants and the construction, operation and building up of the vast system of transmission lines throughout the territory of the company in middle and eastern Tennessee.

Vernon W. Palen, formerly assistant engineer in the engineering bureau of the New York & Queens Electric Light & Power Company, is now connected with the engineering department of the National Electric Light Association, New York. In his new position Mr. Palen will engage in work dealing with problems related to and directly concerning overhead lines and construction. During his affiliation with the New York & Queens utility he directed his attention especially to the design of new primary feeders, secondary design work and the preparation of budget details. Mr. Palen was formerly affiliated with the Commonwealth Edison Company of Chicago.

A. V. Bennett, who has been connected with the West Penn System since 1918, has been elected vice-president of the West Penn Power Company. Before joining the West Penn organization Mr. Bennett was affiliated with the American Water Works & Electric Company, Inc.

H. S. Kerr, chief engineer of the Utah State Road Commission, has been elected president of the Engineering Council of Utah. Mr. Kerr takes a very active interest in the affairs of the engineering fraternity in Utah and has been chief engineer of the Utah State Road Commission since 1926. For the most part his activities have been centered in railroad and railway engineering.

Richard B. Parsons has been appointed underground engineer of the Narragansett Electric Light Company, Providence, R. I., in charge of underground transmission and distribution.

Signor Guido Semenza, general president of the Italian Association of Electrical Engineers, has recently been appointed an officer of the French Legion of Honor, as a mark of appreciation of his work as Italian commissioner at the Hydro-Electric Exhibition at Grenoble in 1925.

Loyall A. Osborne, president of the Westinghouse Electric International Company, has been re-elected chairman of the National Industrial Conference Board at the recent annual meeting held at the Hotel Astor, New York. This will be the third year that Mr. Osborne has held the chairmanship of the board.

## Obituary

Signor Francesco P. Jaccarino, chief electrical engineer of the Società San Georgio of Sestri, Genoa, recently died. He was a leading Italian authority on transformer design and construction.

Ira H. Spencer, president of the Spencer Turbine Company and previously head of the Spencer Turbine Cleaner Company and the Spencer Organ Blower Company previous to their consolidation with the first-named company, died April 28, at the Hartford Hospital, Hartford, Conn. He was an authority on compressed air machines and turbines and an inventor of some note. Mr. Spencer was born in Barkhamsted, Conn., 54 years ago.

John Martin, a pioneer in California hydro-electric development, died in San Francisco, May 23, after a brief illness. He was born in Indianapolis in 1858 and removed to California in 1891. He was identified with a number of the early hydro-electric developments in northern California and was active in organizing gas and electric properties, culminating in the consolidation of many of these into what is now the Pacific Gas & Electric Company. At the time of his death he was chairman of the board of the Mid-Continent Utilities Corporation, serving a large territory between Illinois and Alabama.

William H. Yawger, for many years a vice-president and treasurer of the Weston Electrical Instrument Corporation, Newark, N. J., has resigned from active duty in order better to conserve his health. Mr. Yawger became associated with the Weston company in 1892, just four years after it was organized. His period of active service was 36 years and he still remains on the board of directors with the title of vice-president. Mr. Yawger was born in Lockport, N. Y., and was formerly associated with the Cowles Electric Smelting & Aluminum Instrument Company.

Charles G. Washburn, for many years chairman of the board of trustees of the Worcester Polytechnic Institute and one of the most distinguished citizens of Massachusetts, died suddenly at Lenox, Mass., May 25. He was educated at the Institute and at Harvard College, being a classmate and biographer of the late Theodore Roosevelt, and was a former member of Congress and a manufacturer of prominence at Worcester.

M. Crescitz, formerly vice-director of the Bureau Internationale de l'Union Telegraphique of Berne, Switzerland, died at Chelles, Seine-et-Marne, France, April 19, at the age of 72. It was only last November that he retired owing to ill health, after having been associated with the governmental department of post and telegraphs for more than 50 years.

Arthur D. Dana, organizer and formerly president of the Chicago Fuse Manufacturing Company, died May 25 at his home in New York after a long illness. A native of Marietta, Ohio, and a graduate of Marietta College, Mr. Dana removed to Chicago, where he joined the Linkbelt Machinery Company, of which he was treasurer until 1896. The Chicago Fuse Manufacturing Company, which he formed, became one of the largest manufacturers of electric protecting materials and allied products and Mr. Dana continued as president and chairman of the board until 1924, when he retired because of ill health. He was an intimate friend of Elmer A. Sperry, the inventor, and was associated with him in the formation of the Sperry Electrical Company about 35 years ago, later becoming a director of the Sperry Gyroscope Company. Mr. Dana was actively identified with other industrial enterprises, having been formerly owner of the Moore Drop Forging Company, Springfield, Mass., and a member of the executive committee of the Goodman Manufacturing Company of Chicago before he relinquished his business activities.

Arthur W. Gucker, for several years manager of the Iowa Public Service Company plant in Carroll, Iowa, died suddenly May 6 in his home in that city at the age of 47.

L. J. Kimmel, engineer-inventor, died in Spokane, Wash., April 17 in his forty-eighth year. Mr. Kimmel was the inventor of the Electro-Kold refrigerator and a co-inventor of the No-Kold automatic oil burning furnace. At the time of his death he was vice-president and factory superintendent of the Electro-Kold Corporation in Spokane.

Raleigh C. Thomas, 51 years old, an electrical engineer, was found dead in his sister's apartment in Washington, D. C., May 1. Until recently he was employed by the United States Shipping Board. Formerly Mr. Thomas was prominently identified with the Baltimore city government. He was graduated from Princeton University, where he took an engineering course. After serving as assistant engineer in the Electrical Subway Department of Baltimore he was elected, in 1903, city surveyor. He became chief engineer of the Electrical Commission in 1910, which position he held until 1917, when he received a commission in the Engineer Corps.

John C. Hatzel, president of Hatzel & Buehler, Inc., electrical engineers and contractors, died May 25 at his home in New York in his 69th year. Mr. Hatzel was a native of New York City and was educated at the College of the City of New York. He became an associate of Thomas A. Edison in the early days of electrical development in this country and after serving for four years in the construction department of the Edison Electric Company, in the fall of 1885 he engaged in electrical engineering and contracting, installing central stations and isolated plants and constructing electric railways in various parts of the country. Subsequently he became president of the Western Edison Company, representing the Edison interests in Colorado, Utah and New Mexico. Returning East, he formed a partnership with Joseph Buehler in the fall of 1889, this partnership continuing until 1911, when Mr. Buehler retired. The business was continued by Mr. Hatzel under the old firm name. In the course of his career he was active in the American Institute of Electrical Engineers, the Illuminating Engineering Society, the Electrochemical Society, the New York Electrical Society and the Engineers' Club.

# Financial and Statistical News

## New Capital Issues

During the week ended May 31 the Indiana Hydro-Electric Power Company made an offering of first mortgage 5 per cent gold bonds, series A, to the amount of $3,000,000, the price being 99½ and interest, to yield over 5 per cent. These bonds, dated May 1, 1928, mature May 1, 1958. Proceeds from the sale of these bonds will be applied toward the retirement of all outstanding bonds of the company carrying higher interest coupons.

Thirty-year 6 per cent sinking fund gold debentures, series A, of the Southern Cities Utilities Company were offered at 99½ and accrued interest, to yield over 6 per cent, a piece of financing involving a total of $3,000,000. These debentures, dated Feb. 1, 1928, will mature Feb. 1, 1958. Proceeds from the sale of these debentures and of other securities now being issued will be or have been used to retire outstanding funded debt of the company, to acquire or redeem funded debt and preferred stocks of certain subsidiary companies, to acquire through a subsidiary certain electric properties located in the Dominican Republic and for other corporate purposes.

## March Operations Trend Upward

MARCH operating revenues of electric light and power companies amounting to $157,300,000, expenses aggregating $65,100,000 and an energy production of 6,742,681,000 kw.-hr. are indicated for the country as a whole by monthly reports received and compiled by the ELECTRICAL WORLD. The revenue in December exceeded that of the corresponding month of the preceding year by 6.5 per cent. This was followed by 6.7 per cent in January, 7.9 in February and 7.6 in March. The upward trend seems clear. Slightly irregular figures in February are to be expected in view of the extra day.

Compared with the winter months there was, of course, the usual seasonal decrease both in energy output and in revenue, but in both respects operations were fairly close to the estimated normal based on past growth and observed seasonal variations. The average daily revenue for March was $5,080,000; the normal would have been $5,230,000. Not only has the usual increase occurred, therefore, but it has carried the revenue within 3 per cent of what might have been expected had the rapid expansion of the past five years continued unchecked. The average daily energy production, 217,000,000 kw.-hr., misses the estimated normal by about 1 per cent.

Approximately 40 per cent of the energy came from water power. This is more than the yearly average and reflects the effect of spring stream flow; compared with last year the increase was small—only 6.1 per cent—while the

*Table I—Generation and Distribution of Central-Station Energy in the United States*

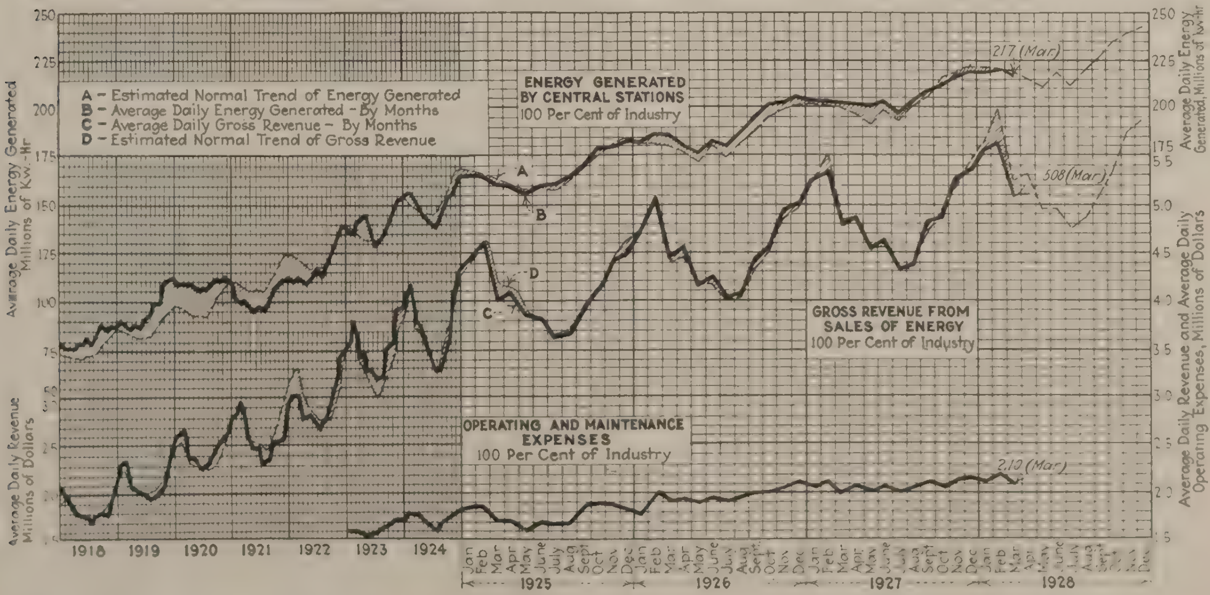
*Data on "energy generated" are those collected and published by the United States Geological Survey for all public utilities minus such data as are collected on energy generated by electric railway companies, reclamation service and manufacturing plants. The data are, therefore, for the electric light and power industry only.

†1928 figures are only approximately comparable with those for 1927, because of changes in classification of certain plants.



## *Table II—Central-Station Financial Operations for Four Months in the United States*

| Jan....... | 2,609,283 | 2,331,140 | +11.9 | 4,158,583 | 3,972,059 | + 4.7 | 3,321,568 | 3,365,461 | —1.3 | 560,871 | 786,062 | —28.6 | 4,955,262 | 3,900,868 | +27.0 |
| Feb....... | 2,463,046 | 2,172,740 | +13.4 | 3,948,950 | 3,533,728 | +11.8 | 3,126,830 | 2,958,797 | +5.7 | 516,557 | 646,558 | —20.3 | 4,896,497 | 3,859,791 | +26.8 |
| March .... | 2,708,730 | 2,551,792 | + 6.1 | 4,033,951 | 3,762,480 | + 7.2 | 3,119,266 | 3,090,984 | +0.9 | 575,684 | 612,657 | — 5.9 | 5,602,443 | 4,312,322 | +30.0 |

*As collected by United States Geological Survey. The data are for the electric light and power industry only.

output from fuel rose by 7.2 per cent and amounted to 4,033,951,000 kw.-hr., requiring the consumption of 3,119,266 tons of coal, 575,684 bbl. of fuel oil and 5,602,443,000 cu.ft. of natural gas; the first increased about 1 per cent, the last 30 per cent and the oil decreased nearly 6 per cent, compared with March, 1927.

Regionally, the most notable departures from the national average occurred in the East and West South Central States, where the year's increase in energy output was 13 and 17 per cent, respectively. The revenue figures likewise reveal the central South as the section having the most rapid gains; the per cent increase, by regions, compared with March, 1927, being as follows:

| | |
|---|---|
| New England .............. | 5.7 |
| Atlantic .................. | 8.0 |
| North Central .............. | 6.3 |
| South Central .............. | 14.4 |
| Western .................. | 9.3 |

Purchase of energy for resale again approached 1,300,000,000 kw.-hr., and was 16 per cent greater than a year ago. Returns on this item are particularly affected by consolidations; data for successive years are therefore only broadly comparable.

---

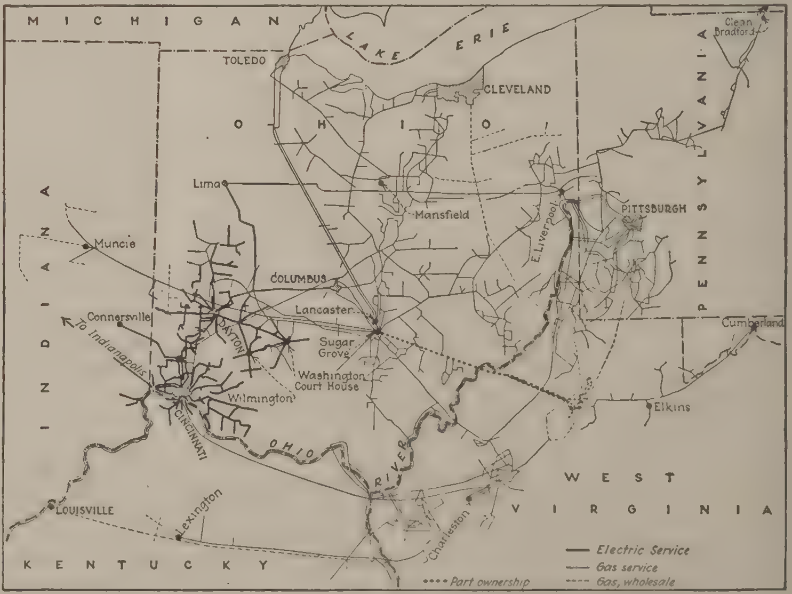
**STANDARD GAS & ELECTRIC SHAREHOLDERS APPROVE CHANGES IN SET-UP.**—At the annual meeting of the Standard Gas & Electric Company held at Wilmington, Del., May 16, the shareholders approved the proposed changes in the prior preference and preferred stocks outlined in the April 21 issue of the ELECTRICAL WORLD. The plan called for the changing of the 500,000 shares of 7 per cent prior preference stock of $100 par value to 750,000 shares of no-par prior preference stock and changing the authorized amount of 8 per cent cumulative preferred stock from 600,000 shares of $50 par value to 1,500,000 shares without par value.

# Columbia Gas & Electric Corporation Consolidates Its Properties

GROSS earnings of more than $96,000,00 class Columbia Gas & Electric Corporation among the nation's important utility groups. Serving a number of rapidly growing areas, chiefly in Ohio, Pennsylvania and West Virginia, this group has gradually built up a number of valuable operating units and has assets of $520,000,000.

Analysis of the corporation's financial position for the past year shows a growth of 5 per cent in gross earnings, while gross earnings from electrical operations alone increased by 12½ per cent. Total operating expenses, including taxes, increased 9.1 per cent, bringing the operating ratio up to 67 per cent, against 65 in 1926. Furthermore, other income dropped off sharply from $3,073,212 to $881,041, due to the cutting off of income from a block of bonds which the corporation sold for construction rather than issuing additional parent company securities.

The no par common stock of the parent company, of which there are



*Electric and gas systems of Columbia Gas & Electric Corporation*

3,372,226 shares outstanding, has had a rapid rise recently from a low this year of $89 to a recent high of $118. This stock pays $5 per share and earned $5.28 last year. Interest charges for the system as a whole were earned more than five times during 1927. The property investment of the system is about $4.72 per dollar of gross revenue, which is somewhat below the average for comparable systems.

During the year Columbia Gas & Electric has continued its policy of consolidating subsidiary operating properties, and, as a result, the financial structure is being greatly strengthened. There have been withdrawn from the hands of the public nine complete issues of bonds and stocks of subsidiary companies. In addition, four bond issues of subsidiaries and one bond issue of a leased company were called for redemption. The process retires some $40,567,672 of securities.

The officers of the Columbia Gas & Electric Corporation pursue an aggressive policy of acquiring neighboring properties whose location and operation make them logical constituents of the system. Several of these were acquired during the past year and have been or will be thoroughly co-ordinated with the system.

## Metropolitan Edison Changes Capital Structure

To provide for improvements and future expansion the Metropolitan Edison Company has increased its authorized capital stock from 900,000 shares, consisting of 400,000 shares of preferred stock and 500,000 shares of common stock, both without par value, to 1,500,000 shares, consisting of 1,000,000 shares of preferred stock and 500,000 shares of common stock, both without par value. The authorized indebtedness of the company has been increased from $50,000,000 to $100,000,000.

In authorizing these changes, stockholders at a special meeting voted favorably for the creation of a new class of preferred stock, to be known and designated as $5 cumulative preferred stock, and to revise the preferred stock of the company into 50,000 shares of $7 cumulative preferred stock, 400,000 shares of $6 cumulative preferred stock, 550,000 shares of $5 cumulative preferred stock.

## Average Output 3,020 Kw.-Hr. per Kilowatt in 1927

Analysis of the recent report of the U. S. Geological Survey on the output of public utility plants during 1927 reveals a wide range in output per average kilowatt of generator capacity.

A summary of the report was published in the Electrical World of April 28, 1928, on page 890. The present tabulation is based on the kilowatt-hour figures there given and on the mean of the installation at the beginning and at the end of the year. The influ-

KILOWATT-HOURS PER KILOWATT IN 1927

| Region | Kw.-Hr. per Kw. |

ence of regional conditions on the amount of installation required to produce a given annual output is evident.

## Electric Power in Canada

Almost 99 per cent of the electrical energy output of central stations in Canada in 1926 was hydro-electric, according to a preliminary report on the census of the central-station industry for 1926 recently issued by the Dominion Bureau of Statistics. The energy output was 19 per cent greater in 1926 than in 1925, the rapid growth being due in considerable degree to the pulp and paper and to the mining industry. The estimated horsepower purchased by the former from central stations shows an increase of more than 160 per cent between 1922 and 1926. Most of this is 24-hour power. The numerous small fuel plants were more important than their 1 per cent of the output would imply, by serving 57,000 customers.

The report gives data relating to the individual provinces as well as numerous statistical items for the industry in Canada as a whole, only a few of which can be here quoted.

GROWTH OF CENTRAL STATION INDUSTRY IN CANADA

|  | 1926 | 1925 |

## Economic Progress Reviewed by Industrial Board

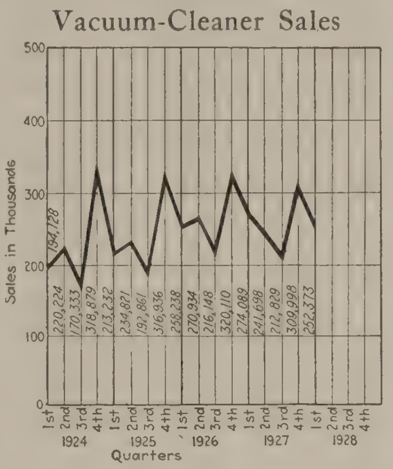
A review of today's most pressing business problems and of the contributions of science and engineering to economic progress was the outstanding feature of the twelfth annual meeting of the National Industrial Conference Board, held in New York, May 17. Particularly notable were addresses by Gilbert H. Montague, declaring that the Sherman law was being satisfactorily modified by interpretation, and by Charles H. Herty on the great contribution that chemistry has made to economic progress. Prof. Michael I. Pupin praised the college professor as the father of the electrical industry and the creator of that scientific idealism which he pictured as a proper policy for industry.

Mr. Montague, a New York attorney who is an authority on the Sherman law, declared that legislation was being constantly modified by the increasing liberality of court decisions on consolidations and combinations, by action of the Federal Trade Commission and by a liberal attitude on the part of the Department of Justice. He declared emphatically that it was not true that American business cannot thrive under the present anti-trust laws. He believes that the modifications are such and the tendency so liberal that we should not attempt to tamper with the Sherman law by amendment and thus set up additional bureaucratic machinery and create unsettlement until the meaning of the new amendments can be determined. He heartily recommended two books on combinations and consolidations publishd by the National Industrial Conference Board, and a third, now in press, to be put out by the same organization.

Magnus W. Alexander, president of the board, discussed thoroughly the various estimates of unemployment put out during the last six months, showing how the various figures were built up and proving the unreliability of the figures of 4,000,000 and more unemployed. He made a satisfactory defense, also, of the thesis that the mechanization of industry should not be curtailed because of any temporary effect it might have on the unemployment problem.

Virgil Jordan, chief economist of the board, made the point that those who expect our private foreign loans to be repaid when due are sure to be disillusioned. He believes that these loans will be funded and refunded indefinitely, just as are the bonds of large corporations in the United States. This he held to be the normal expectation. Nevertheless, our large loans abroad set up a new financial relationship between the rest of the world and the United States—a relationship into which we were thrust in the very brief four years of the war and for which, therefore, we have had no preparation in the way of adequate experience in international finance. The resulting problems are intricate and difficult. They must have the very deepest study by industrialists and business men. Otherwise we shall learn by bitter experience.

Loyall A. Osborne, president of the Westinghouse Electric International Company, was re-elected chairman of the board and Magnus W. Alexander president and chief executive of the organization. The other officers are as follows: Vice-chairmen, Charles Cheney, president Cheney Brothers, South Manchester, Conn.; Irenée du Pont, chairman finance committee E. I. du Pont de Nemours Company, Wilmington, Del.; Herbert F. Perkins, first vice-president International Harvester Company, Chicago; George S. Harris, president Exposition Cotton Mills, Atlanta, Ga.; treasurer, Fred I. Kent, director Bankers Trust Company, New York. The executive committee will be composed of the officers of the board and the following members: William D. Baldwin, chairman Otis Elevator Company; A. Farwell Bemis, chairman Bemis Brothers Bag Company, Boston; Cornelius F. Kelley, president Anaconda Copper Mining Company, New York, and William H. Nichols, Jr., president General Chemical Company, New York.



Vacuum-cleaner sales by quarters during 1924, 1925, 1926, 1927 and the first quarter of 1928. (Data supplied by Vacuum Cleaner Manufacturers' Association.)

## Helium Now Available in Commercial Quantities

Helium, heretofore a rare element and not obtainable in the open market, is now available in commercial quantities. Although the most important use of helium is for inflating dirigible and passenger balloons, it has an increasing use in industry. It is being used for filling radio tubes and glow lamps and tubes for signs and as a cooling medium in

## *Imports of Electrical Apparatus Into the United States by Commodity and by Country of Origin for the First Quarter of 1928*

(Data furnished by the Bureau of Foreign and Domestic Commerce)

| Article | First Quarter |
|---|---|

electric transformers and high-speed generators. It also is used as a non-oxidizing gas in annealing processes and metallurgical operations, and as a damper for scientific instruments because of its high viscosity.

Helium has been made available commercially by the discovery of new natural gas fields having a higher helium content and the development of an improved process of extraction by the Helium Company, whose plant is at Dexter, Kan., with headquarters at Louisville, Ky.

for a new addition to cost $300,000. The U. S. Coast and Geodetic Survey, Washington, D. C., will receive bids until June 22 for construction of a steel Diesel-electric propelled survey ship of about 770 tons displacement; separate bids will be received at the same time for furnishing main propelling machinery, pumps, windlass, capstan, boat hoist, etc.

# Market Conditions

BUYING is reported at a satisfactory level in the industry. Industrial business is good and inquiries presage future sales. Fractional-horsepower motor sales are said to be exceeding expectations largely owing to the increased demand for domestic appliances. Important projects include a can manufacturing plant at Chicago to cost more than $500,000; a new rayon mill near Richmond, Va., to cost $1,500,000, and a paperboard mill at Baltimore, Md., to cost $300,000.

In New England buying is at a good level and small motors are in demand. Maine and New Hampshire plants were active in ordering poles and line material. Industrial plant business looms up as the important factor in business in the Eastern district. Sales of industrial control apparatus are reported by one manufacturer as about 5 per cent better than they were last year. The demand for street-lighting equipment has improved in the New York metropolitan district, Buffalo, Philadelphia and Chicago. In the Southeast a good volume of business made up of many small orders is reported. A steel mill in Alabama ordered $65,000 worth of motor equipment and a bleachery in South Carolina purchased $15,000 worth of apparatus. Another bleachery plant to be built in South Carolina calls for an expenditure of $2,000,000, of which amount $300,000 will cover the electrical installation. A decidedly better tone is noted in the St. Louis district, and manufacturers report more business in sight. An order for two turbine units amounted to $80,000. Industrial business is better in the Middle West and conditions continue to improve. On the Pacific Coast many pole and crossarm inquires are reported including one for $50,000. Pump and motor business especially has been good owing to flood conditions in eastern Washington and Idaho.

## *Expansion of Sales Noted in Eastern District*

Sales continue on a satisfactory basis in the Eastern district, with industrial sales maintaining the lead over central-station and affiliated business. There is a pronounced demand for motors in larger sizes up to 250 hp. from iron and steel plants, textile mills and cement mills, with the New England district a prominent factor in commitments. Inquiries are holding up well for early future sales. Business in fractional-horsepower motors is said by one manufacturer to be exceeding all expectations for the year. There has been a marked increase in sales for talking machines, washing machines and other domestic appliances, and the first six months of 1928 will show an encouraging advance over the corresponding period a year ago. A water company at Pittsburgh, Pa., has placed an order for a turbo-generator unit to cost about $50,000, for a pumping station installation, and Evansville, Ind., has contracted for a 750-hp. geared turbine unit for extensions in its municipal waterworks.

Transformer business has been advancing for the past few weeks, with industrial commitments on a good level. Central-station business in that line shows a little decline, with utilities in the metropolitan district now coming into the market. A leading manufacturer reports an order from a hospital in northern New York for transformer with switchboard panel, etc., to cost close to $20,000. A maker of industrial control apparatus says that sales for the present year are running at 5 per cent or better than the average for the same period in 1927, with the gain particularly noticeable in the New York and Philadelphia districts. Construction operations in the Eastern district include the following:

Hansen's Laboratory, Inc., Little Falls, N. Y., manufacturer of food products, will build an addition to cost about $300,000. The American Enka Corporation, New York, plans a power plant at its proposed rayon mill near Richmond, Va., to cost $1,500,000. The Corn Products Refining Company, New York, plans a refining plant in Sao Paula, Brazil, to cost $1,000,000. Automotive Standards, Inc., New York, has purchased property with buildings at Newark, N. J., for plant to cost $400,000. The Public Service Electric & Gas Company, Newark, N. J., is securing a right-of-way for a proposed transmission line in Essex, Union and Middlesex Counties. The Direct Ink Ribbon Company, Camden, N. J., plans a plant to cost $85,000. Harrisburg, Pa., is asking bids until June 7 for fire alarm and police cable lines.

The Pennsylvania Railroad Company is carrying out a shop expansion program at Wilmington, Del., to cost $200,000, and will remove Pavonia shops at Camden, N. J., to that location. The Bureau of Supplies and Accounts, Washington, D. C., will receive bids until June 5 for generator units, impulse cable assemblies, etc., for Philadelphia navy yard (Schedule 9111). The Chesapeake Paper Board Company, Baltimore, Md., will ask bids about June 15

## *Prices of Copper, Lead and Zinc Advance*

Copper has sold in excellent volume and now appears to be firmly established at 14¾ cents, Connecticut Valley. More than usual activity in lead is reported and the New York price is now 6.30 cents compared with 6.10 cents a week ago. Buying of zinc has been almost non-existent, but some sellers are asking 6.15 cents and there is no inclination on the part of producers to make concessions. For the sixth consecutive week copper has sold in excellent quantity.

NEW YORK METAL MARKET PRICES

| | May 23, 1928 Cents per Pound | May 29, 1928 Cents per Pound |
|---|---|---|
| Copper electrolytic | 14.375 | 14.525 |
| Lead, Am. S. & R. price | 6.10 | 6.30 |
| Antimony | 11.125 | 11.0 |
| Nickel, ingot | 35 | 35 |
| Zinc spots | 6.475 | 6.475 |
| Tin, Straits | 51.625 | 50.625 |
| Aluminum, 99 per cent | 24.30 | 24.30 |

Base copper wire price May 29, 1928, 16⅝ cents.

## *Industrial Business Better in Middle West*

General business in the Middle West continues to improve. Industrial activity is not quite as spotty and with the stiffening up of the metal market, better business conditions are anticipated. The railroads report a varied movement of commodities and some hope is evidenced recently with regard to the coal situation. Employment conditions have improved somewhat. Interesting orders placed by utility companies included evaporator equipment, a feed water heater, a revolving car dumper, six induced draft fans, one railroad track scale and 500,000 lb. of bus bar copper. Construction projects are as follows:

The Mills Novelty Company, Chicago, plans a plant for coin machine manufacture, to cost $100,000. The Harrisburg Packing Company, Harrisburg, Ill., plans a packing plant to cost $100,000. The Construction Division, Veterans' Bureau, Washington, D. C., will receive bids June 12, for ash-handling equipment for hospital at Maywood, Ill. The Iowa Public Service Company, Ft. Dodge, Iowa, plans improvements in the power plant at Charles City, Iowa, to cost $100,000. Chillicothe, Iowa, plans a municipal power system. The Detroit Edison Company, Detroit, Mich., will build additions to power substations at Cortland, Grand River, Amsterdam, and Hart, to cost $200,000. The Detroit Macaroni Manufacturing Corporation, Detroit, Mich., will build a plant, to cost $175,000. The O. B. McClintock Company, Minneapolis, Minn., manufacturer of fire and burglar alarm systems, etc., plans a plant to cost $80,000.

The Zinsmaster Baking Company, Minneapolis, Minn., will build a baking plant to cost $170,000. The Great Northern Railway Company, St. Paul, Minn., plans a call for bids for the power plant and repair shops at Fargo, N. D., to cost $100,000. The Cleveland, Cincinnati, Chicago, & St. Louis Railroad Company plans repair shops at Bellefontaine, Ohio, to cost $155,000. The Contracting Officer, Material Division, Air Corps, Wright Field, Dayton, Ohio, will receive bids June 5, for 763 generator units (Circular 333). The Lakeside Cheese Company, Plymouth, Wis., will build a plant at Loyal, Wis., to cost $100,000. The Madison Silo Company, Madison, Wis., plans a plant to cost $75,000. The Hudson Manufacturing Company, Minneapolis, Minn., plans a plant for the manufacture of barn and dairy equipment at Waukesha, Wis., to cost $60,000. St. Paul, Minn., plans an ornamental lighting system on Concord Street. The town clerk, Afton, Iowa, will receive bids until June 15, for an electrical distribution system.

## *Active Business Reaches Good Volume in Southeast*

Satisfactory activity is reported in the electrical field in the Southeast with the volume sustained by increased small business. A power company in Georgia ordered bare and weather-proof copper wire amounting to $15,500, while a company in Tennessee placed orders for a 3,000-kva. transformer and distribution transformers amounting to $3,000. A small company in Georgia ordered small power transformers amounting to $2,500, while another company in the same state purchased small power and distribution transformer equipment totaling $3,600. A central-station company recently purchased control batteries costing $6,000. The demand for control batteries is active.

A steel mill in Alabama ordered motor equipment amounting to $65,000 and a bleachery plant in South Carilona purchased dyeing and bleaching equipment costing $15,000. A cotton mill in Georgia bought pole line materials amounting to $5,000 for use in its mill village distribution system, and an automobile assembling plant in the same state purchased an industrial truck costing approximately $5,000. Engineering contract was closed this week for a finishing plant and bleachery to be constructed in South Carolina, the plant to represent an expenditure of $2,000,000 with approximately $300,000 going into the electrical installation. Engineers are also at work on a 20,000-spindle cotton mill for Tennessee. Construction projects are as follows:

The Gulf Fertilizer Company, Tampa, Fla., plans a mill to cost $150,000. The Gentile Brothers Packing Company, Haines City, Fla., plans a cold storage plant with new fruit canning factory to cost $100,000. The Sixth Vein Coal Company, Madisonville, Ky., plans expansion in properties to cost $75,000. The B. V. May Hosiery Mills, Inc., Burlington, N. C., will build an addition to cost $400,000. The Atlantic Ice & Coal Company, Atlanta, Ga., plans an ice plant at Knoxville, Tenn., to cost $100,000. The Virginia Public Service Company, Charlottesville, Va., is negotiating for the purchase of the municipal plant at Staunton, Va. Huntsville, Ala., plans an ornamental lighting system.

## *Buying in New England at a Good Level*

Industrial sales volume showed improvement in the New England district, with small motor sales at a high level. An interesting order amounting to over $80,000 was reported. A number of industrial plants are equipping on a fairly extensive scale. A paper company recently placed an order for motors and control amounting to over $40,000, and a number of smaller orders are recorded. Small switch sales are good and negotiations have increased, particularly concerning heavy power apparatus.

Central-station supplies are moving well. Orders for poles and line material lead with buying active among Maine and New Hampshire plants. During the past week transmission line equipment sales increased. Projects for electric lighting are increasing, and street lighting is active. Boston plans to expend $125,000 for electric automatic progressive timing traffic signals. Interest in structural welding is increasing. Jobbing conditions are uneven. Electric ranges are in strong demand. Construction projects are as follows:

The New York, New Haven & Hartford Railroad Company has acquired a tract of land at John and Water Streets, New London, Conn., and plans a power plant. The Connecticut Power Company, New London, Conn., plans an equipment storage and distributing plant at Waterford, Conn., to cost $40,000.

## *Decidedly Better Tone Noted in St. Louis*

General conditions show an improvement in the St. Louis district. An order was placed for two turbo-generator units for the western part of the district at a cost of $80,000. The St. Louis water department bought a lot of electric driven service pumps amounting to $7,000. Another order from a paper company for motors and control apparatus amounted to $6,000. There is an increasing demand for line construction materials which are being shipped mostly to the southwestern part of the district. Manufacturers report more business in prospect and a decidedly better tone throughout the district, particularly in the south and west. Construction projects are as follows:

The Ward Furniture Manufacturing Company, Fort Smith, Ark., will build a factory to cost $85,000. The Barnes Dairy Products Company, Rogers, Ark., plans a milk plant to cost $65,000. The United States Engineer Office, New Orleans, La., is taking bids until June 6, for one electric-driven air compressor complete (Circular 265). The Shreveport Packing Company, Shreveport, La., plans a packing plant to cost $80,000. The Meeker Advertising Company, Joplin, Mo., plans a factory for the manufacture of display equipment, to cost $100,000. The St. Louis Electric Terminal Railway, St. Louis, Mo., plans a terminal and freight building to cost $1,000,000.

Stanberry, Mo., plans the installation of a municipal power plant. The General Baking Company, New York, N. Y., plans a baking plant at Oklahoma City, Okla., to cost $175,000. The Texas Company, Houston, Tex., plans expansion in the Port Arthur oil refinery to cost $3,000,000. The Arkansas-Missouri Power Company, Blytheville, Ark., has secured franchise at Blytheville, Ark., and plans extensions in transmission lines. The Arkansas Power & Light Company, Little Rock, Ark., will build a 33,000-volt transmission line between Gurdon and Camden, Ark. Durant, Okla., plans extensions in its ornamental lighting system.

## *Business in Good Volume on Pacific Coast*

Many pole and crossarm inquiries are reported on the Pacific Coast. They are mainly for carload shipments to various points. An inquiry of the Pacific Gas & Electric Company, approximates $50,000, and another covers 1,000 assorted treated poles, mainly 30 ft. and 35 ft., for the Hawaiian Islands. The Southern Pacific Company has just completed the installation of four selective teletype printers in the Los Angeles yard to record train departures and contemplate similar installations in San Francisco and Oakland. The electrical material is valued at about $7,500 per job. Motor orders for industrials are good typical orders though larger than average.

Flood conditions in eastern Washington and Idaho, occasioned by melting snow in the mountains preceded by heavy rains, brought considerable pump and motor business to dealers in Spokane, Seattle and Tacoma. Other sales reported include about 75 motors from 100 hp. down for sawmills and allied industrials; 6 2,500-kva. transformers for track substations for the Great Northern Railway in the Wenatchee Valley; 3 55,000-volt oil circuit breakers and a number of 15,000-volt breakers for a central-station company in the Puget Sound district. Construction projects are as follows:

Cold storage plants are planned for Wenatchee and Yakima. Paper bag factories are planned in Vancouver, Wash., and St. Helens, Ore. The Centralia Lumber Company plans a large manufacturing plant. The North Corona Land Company, 528 South Hill Street, Los Angeles, plans a steam power plant at Norco, Calif., to cost $130,000. Sacramento, Calif., plans installation of underground conduit system for all street lights. The Union Ice Company, San Francisco, plans an ice plant at San Jose, Calif., to cost $200,000. W. L. Soens, Durango, Colo., and associates have applied for permission to build a hydro-electric power plant at Bayfield, Ignacio, and vicinity, to cost $200,000. The Weyerhaeuser Lumber Company, Tacoma, Wash., plans a lumber mill near Klamath Falls, Ore., to cost $400,000.

Centralia, Wash., has applied for permission to build a hydro-electric plant on the Skookumchuck River, to cost $300,000. The Puget Sound Power & Light Company, Seattle, Wash., has a permit for a switching station. The Great Northern Railroad Company, Seattle, Wash., plans improvements in shops at Interbay yard, to cost $400,000. Sellers & Stone, Inc., Yakima, Wash., will build a cold storage plant for railroad car service to cost $150,000. The Pacific Gas & Electric Company, San Francisco, will make extensions in transmission lines between San Rafael and Petaluma, Calif. The Commonwealth Utilities Corporation, Colorado Springs, Colo., plans a transmission line to the municipal airport, Calhan and vicinity. Morton, Wash., will build a transmission line from La Grande, in co-operation with the Rainier National Park. Los Angeles and Santa Cruz, Calif., plan ornamental lighting systems.

# Activities of the Trade

## New Merger Groups Makers of Transmission Material

The National Electric Products Corporation has been organized and has acquired the business of the National Metal Molding Company of Pittsburgh and Economy, Pa., the American Copper Products Corporation of Bayway, N. J., and the British American Metals Company of Plainfield, N. J. The National Metal Molding Company manufactures rigid conduit, outlet boxes and fittings, metallic and non-metallic flexible conduit, armored and rubber-covered cables and wires and metal molding. The American Copper Products Corporation makes bare copper wire and rods, weatherproof wire and transmission cable. The British American Metals Company manufactures condenser tubes and brass and copper pipe. The new organization thus becomes a large copper-consuming unit. Through its subsidiaries the new company also holds the majority of the stock of the Habirshaw Cable & Wire Corporation with mills at Yonkers, N. Y., and Bridgeport, Conn.

The new organization states that the grouping makes up a combination of non-competitive manufacturers whose products or lines are more or less supplemental and which in their entirety may be described broadly as covering an entire industry. The National Electric Products Corporation has been formed under the laws of Delaware with an authorized capital stock of 300,000 shares of no par value common and $5,000,000 of 6 per cent cumulative dividend preferred stock. None of the preferred stock will be issued at this time and there will be no public offering of the stock. The officers of the new corporation are: W. C. Robinson, chairman of the board; Wylie Brown, president; F. S. Jerome, treasurer; I. A. Bennett and H. H. Robinson, vice-presidents, and A. L. Robinson, treasurer. The board of directors will consist of all of the officers and O. F. Felix and C. F. Holdship of Pittsburgh, H. C. Carpenter of Elizabeth, N. J., and C. J. Gleason of New York.

---

The Ideal Commutator Dresser Company, Sycamore, Ill., announces that it has improved and added many special attachments to the Ideal combination blower and suction devices.

The National Electric Heating Company, Boston, manufacturer of "Nehco" industrial electric heating equipment, announces the opening of an office in the Graybar Building, 420 Lexington Avenue, New York City, in charge of Robert A. Carleton. E. S. Guild, formerly chief engineer of the Carleton-Mace Engineering Corporation, has joined the organization as electrical engineer and Fred V. Hadley has been appointed New England representative with offices at 127 Federal Street, Boston.

---

## Altorfer Bros. Makes Large Shipments of Washers

For the second time in three weeks a train load of ABC washers, running as a special extra fast freight, was dispatched from the Altorfer Bros. Company factory in Peoria, Ill. The first train load was sent to the Southwest while the second went to the Eastern market. Early last year the Altorfer Bros. Company brought out, under the trade name "ABC Spinner," a washer with a porcelain tub. At the same time, to assure adequate production of a uniform, high standard porcelain, a complete porcelain department was installed at the factory, at a cost of approximately $250,000.

---

The Allis-Chalmers Manufacturing Company, Milwaukee, announces that its Grand Rapids, (Mich.) branch office has been moved to 310 Building and Loan Building. This office is in charge of G. C. Culver.

The Excel Electric Company, Muncie, Ind., manufacturer of home electric appliances, announces that A. C. Crandall has been made sales manager. Mr. Crandall was formerly with the Central Indiana Power Company of Indianapolis.

The Wagner Electric Corporation, St. Louis, announces that E. D. Pike is now manager of its San Francisco branch sales office. Mr. Pike has been with the company for twenty-six years and until recently was in charge of the company's Pacific coast service operation.

The Dampney Company of America, Hyde Park, Boston, manufacturer of "Apexior" protective coatings for power plant equipment, announces the appointment of C. J. Hunter as its Philadelphia district sales manager. Mr. Hunter will have offices in the Philadelphia Bourse Building and will look after the company's interests in eastern Pennsylvania, southern New Jersey, Delaware, eastern Maryland, District of Columbia and northern Virginia.

## Fulton Iron Works Buys Foos Engine Company

Following the acquisition of a substantial stock interest in the Foos Engine Company of Springfield, Ohio, the Fulton Iron Works Company of St. Louis has purchased the Foos company, using common stock of the Fulton company. The announcement that a substantial stock interest was acquired by the Fulton company was made in the Oct. 29, 1927, issue of the Electrical World. The Foos Engine Company manufactures Diesel oil engines from 10 hp. to 300 hp. The Fulton company will operate the Springfield plant as a branch.

Harry J. Steinbreder, president of the Fulton concern, said that at the present time, exclusive of the Foos business the company has on hand sufficient orders to operate full capacity for the next four months. "Shipments for the company's fiscal year ending in June should exceed any one of the last five years and will in all likelihood be more than double the shipments of the last fiscal year," said Mr. Steinbreder.

---

The Silvray Company, Inc., 55 West Sixteenth Street, New York City, manufacturer of Silvray indirect bulbs and "Spraylite," announces the removal to its new and larger plant, located at 53 West Fourteenth Street, New York City, where four times the present capacity will be available.

The Buffalo Foundry & Machine Company, Buffalo, N. Y., manufacturer of "Buflovak" vacuum dryers, evaporators and chemical apparatus, announces the appointment of O. S. Sleeper as engineer in charge of special development work. Mr. Sleeper has for the past seven years conducted the O. S. Sleeper Company, manufacturing similar equipment.

The Oliver Iron & Steel Corporation, Pittsburgh, announces the appointment of C. A. Heiser as district manager at Dallas, Tex., with headquarters at 409 Browder Street. Mr. Heiser, formerly assistant sales manager of the Southwest General Electric Supply Company at Dallas, will have charge of the line material, bolt, nut and rivet departments.

The McGraw Electric Company, Omaha, Neb., jobber, announces the purchase of the "Clark" electric water heater business from the Stoughton Manufacturing Corporation of Stoughton, Wis. The business will be conducted from the general office at Omaha and the manufacturing plant will be continued at Stoughton, Wis., by the designer of the Clark electric water heater. A. E. Julian, who will continue as sales manager of the water heater business, will move to Omaha, making his headquarters in the McGraw building. The executive management of the business will be under the direction of Arthur J. Cole, vice-president and general manager of the McGraw Electric Company.

# New Equipment Available

## Outdoor Potential Detector

A means of indicating potential on high-tension transmission lines at points where no potential transformers are used is a recent development by the Westinghouse Electric & Manufacturing Company. This is accomplished by means of a type O N static glow outdoor potential detector.

The detector consists of a vacuum type static glow lamp mounted in standard fuse clips and inclosed in a metal case having a glass window. It is suspended from the line conductor by a clamp in such a manner that the lamp is visible from the ground. One terminal of the glow lamp is connected to the line conductor through the clamp and the other is fastened to a brass rod antenna suspended from the case. The detector is applicable to line voltages from 4.5 kv. to 220 kv.

## High-Frequency Grinder

The addition of high frequency models to its line of grinders is announced by Forbes & Myers, Worcester, Mass. These new models are identical with the previous bench and floor type grinders made by the company with the exception that they are built to operate at higher speeds. The new grinders are now being built in sizes from ¼ hp. to 2 hp. for all commercial high frequencies and for maximum speeds of 12,000 r.p.m.

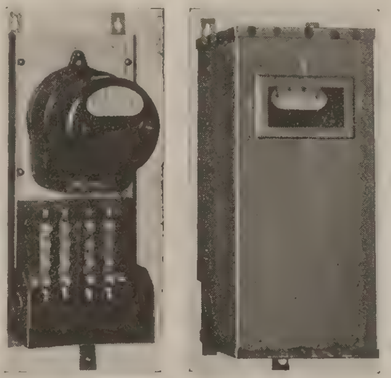
The motor is of the high frequency induction type with a long spindle, the motor armature and wheels being mounted directly on the spindle. It has four ball bearings, one close to each end of the spindle and one on each side of the motor. The space between the two bearings on each side of the motor is a large chamber for grease. The rotor is provided with aluminum bars and rings welded together. The company also manufactures a line of frequency changers for supplying these high frequency motors.

## Lever Operated Switch

A new switch, designed especially for splined shaft or shipper rod operation, is announced by the Cutler-Hammer Manufacturing Company, Milwaukee. This switch is for use as a pilot circuit control device on lathes, textile machinery and other equipment where starting and stopping of the machine is to be governed by a splined shaft, shipper rod or similar device. Low voltage protection is provided. Some of the features claimed by the manufacturer are: Non-stubbing contacts; shear pin to protect the mechanism; few parts and simple construction; operating lever which can be placed in any one of four operating positions 90 deg. apart, to suit any installation requirement; long, steel-to-bronze main bearing with oil hole; small size; fully inclosed in heavy steel case, and a cover which can be removed by loosening only two screws. The switch is designed especially for three-wire control, but also can be used for two-wire control on pilot circuits up to 550 volts.

## Outdoor Meter Box

A new type of meter box which makes it possible to mount residential meters out of doors for easy reading is announced by the Square D Company, Detroit, manufacturer of safety switches and other electrical control equipment. The case, finished in clear enamel, is of 16-gage steel, electrically welded, with a double strength window glass cemented in. The assembly includes a 60-amp. test block, a sealing stud at the bottom of the box, and a meter board of wood which permits the mounting of meters with differently spaced mounting holes. Two heavy steel strips are welded to the back of the box, offset to hold it away from the wall. The illustration shows the meter box with the cover removed and in place.



*Meter box which permits outdoor installation of watt-hour meter*

The distribution fuse box and service entrance switch are installed in the basement exactly as in the case of indoor metering. Service is brought from the pole directly to the meter box, which is mounted at the most convenient location on the outside wall of the house. The meter itself is protected, as the box is moisture-proof.

## Marine Type Instruments

A line of marine type ammeters and voltmeters, designed for use on shipboard or in mines or other locations where damp conditions may exist, has been developed by the Westinghouse Electric & Manufacturing Company. They operate on the D'Arsonval principle and are known as the type SX. Several features incorporated in these instruments are sapphire jewels, terminals in rear of instrument and accuracy within 1 per cent of full scale. The voltmeters have a range of 150 to 750 volts and the ammeters are available in a standard range of capacities from 50 amp. to 8,000 amp.

## Automatic Reclosing Feeders

A new line of automatic reclosing feeder equipment, arranged in the form of completely inclosed cubicles, has been placed on the market by the General Electric Company. These cubicles contain a circuit breaker and disconnecting switches, and are operated automatically by relays mounted on the front panel. The new cubicle construction has been designed to exclude dust and dirt from the operating parts, and to provide the feature of safety which is so important in the dead front type of switchboard apparatus now coming into use for inside installation.

Circuit breakers and disconnecting switches are mounted on a channel frame which also supports the walls of the cubicle. The front panel is arranged in the form of a door, and on it are mounted the necessary relays and meters for providing the automatic reclosing feature. On the back of this panel is located all of the control wiring, which is easily accessible. A rear door affords a means of conveniently inspecting breakers and all breaker parts. The cubicles are made in standard sizes and in ratings up to 7,500 volts. They may be arranged side by side to form a continuous switchboard of the completely inclosed type.

INSULATOR PINS.—A new series of pins known as the Locke "Redhead" and Locke "Leadhead" pins, has been placed on the market by the Locke Insulator Corporation, Baltimore. These pins consist of a cast-iron base with a steel through bolt and are intended for use with insulators having the standard 1⅜ in. N.E.L.A. pin hole. The "Redhead" pin is for use only with insulators having perfect metal threaded pin holes. The "Leadhead" pin may be used with these insulators or with any insulator having the 1⅜ in. standard N.E.L.A. pin hole.

PANELBOARD.—A new type of panelboard, known as the "Security," and which is of molded base unit construction, has been placed on the market by the Penn Electrical Company, Irwin, Pa. The fuse blocks are separate from the switch bases and the two types of fuse blocks are interchangeable. For instance, a panelboard arranged for cartridge fuses can be converted readily to a plug-fused panelboard. The line is made in the live face and safety construction types. The molded blocks will take either two double-fused circuits or four single-fused. The tumbler switches are of the heavy duty type and the switch plates are of molded bakelite.

# Electrical Patents

*Announced by U. S. Patent Office*

(Issued May 8, 1928)

1,669,039. Electric Soldering Iron; L. S. Brach, East Orange, N. J. App. filed Dec. 4, 1925.

1,669,082, 1,669,083. Synchronous Motor; V. A. Fynn, St. Louis, Mo. Apps. filed June 12, and Aug. 2, 1926. Adapted to carry variable load at synchronous speed.

1,669,097. Control of Electric Circuits; H. A. McCrea, Schenectady, N. Y. App. filed July 28, 1927. Providing for the disconnection of a faulty portion of a circuit.

1,669,099. Automatic Arc Welding Machine; P. O. Noble, Fort Wayne, Ind. App. filed March 26, 1927.

1,669,106. Electric Switch; J. F. Tritle, Schenectady, N. Y. App. filed Dec. 6, 1924. "Trip free" type.

1,669,107. Automatic Controller; L. A. Umansky, Schenectady, N. Y. App. filed May 9, 1927. For the driving means of a driven element, the number of rotations of which it is desired shall bear a predetermined ratio to the number of rotations of another driven device.

1,669,109. Induction Furnace; J. M. Weed, Schenectady, N. Y. App. filed April 19, 1923.

1,669,113. Stator Construction for Dynamo-Electric Machines; A. P. Wood, Schenectady, N. Y. App. filed Feb. 19, 1927. Employing frame plates to clamp bars which engage the sides of the stator teeth to stiffen them so as to render the use of clamping covers unnecessary.

1,669,114. Electric Heater; C. C. Abbott, Pittsfield, Mass. App. filed March 19, 1927. For ovens and the like.

1,669,120. Combined Switch and Plug Receptacle; F. C. De Reamer, Bridgeport, Conn. App. filed May 8, 1923.

1,669,122. Electric Socket; J. B. Downing, East Orange, N. J. App. filed Oct. 6, 1924.

1,669,125. Electric Switch; H. G. Hartmann, Schenectady, N. Y. App. filed Feb. 1, 1924. Latching device for disconnecting switch.

1,669,126. Spot Welding; W. Hopp, Heiligensee, Germany. App. filed Feb. 7, 1927.

1,669,129. Electrode; W. Irby, Lynn, Mass. App. filed Jan. 7, 1927. For use with the luminous type of arc.

1,669,132. Slip-Regulator Control; G. H. Jump, Buffalo, N. Y. App. filed June 21, 1926. For automatically regulating the slip of an alternating current motor so as to permit a flywheel or other inertia device connected with the motor to assist in carrying peak loads thrown on the motor.

1,669,134. Molded Commutator; H. T. Kelso, Fort Wayne, Ind. App. filed Dec. 3, 1927.

1,669,142. Static Frequency Changer; M. Osnos, Berlin, Germany. App. filed Oct. 20, 1925.

1,669,147. Vapor-Electric-Arc Apparatus; C. A. Sabbah, Schenectady, N. Y. App. filed July 21, 1926.

1,669,148. Electric Control System; C. Schiebeler, Berlin, Germany. App. filed April 28, 1926. For hoisting installation.

1,669,149. Protective Arrangement; O. C. Traver, Schenectady, N. Y. App. filed May 4, 1926.

1,669,150. Speed Regulation of Synchronous Motors; L. A. Umansky, Schenectady, N. Y. App. filed May 11, 1926.

1,669,154. Protective Relay; W. R. G. Baker, Schenectady, N. Y. App. filed Sept. 14, 1925.

1,669,157. Electric Fuse; G. R. Brown, Bridgeport, Conn. App. filed July 30, 1926. Inclosed fuse.

1,669,159. Phase Indicator; R. D. Duncan, Jr., East Orange, N. J. App. filed July 21, 1925.

1,669,162. Motor-Generator Control; P. W. Forsberg, Schenectady, N. Y. App. filed Nov. 3, 1925. Sets employed in electric locomotive or similar service.

1,669,163. Electricity Meter; J. Harris, La Fayètte, Ind. App. filed Dec. 27, 1928.

1,669,177. Electricity Meter; F. Scott, La Fayette, Ind. App. filed May 9, 1927.

1,669,190. Conduit Fitting; R. P. Dunmire, Erie, Pa. App. filed Oct. 30, 1925.

1,669,192. Hospital Appliance; J. C. Fischer, Wauwatosa, Wis. App. filed June 12, 1926. Distributing cart with food warming equipment.

1,669,193. Electric Extension Plug; J. A. Fourney, Oakland, Calif. App. filed Nov. 9, 1922.

1,669,202. Pressure-Controlled Switch; M. Lassen, Detroit, Mich. App. filed Oct. 17, 1924.

1,669,209. Lamp Socket; J. Ribaysen, Chicago, Ill. App. filed April 30, 1925.

1,669,240. Electric Switch; O. Hammerstrom and H. O. Engstrom, Bridgeport, Conn. App. filed July 15, 1924.

1,669,274. Electric Switch; C. E. Anderson, Stratford, Conn. App. filed Oct. 21, 1921. Toggle type.

1,669,283. Electric Switch; J. R. Carlson, Hartford, Conn. App. filed Nov. 10, 1922. Rotary snap switch.

1,669,298. Rotary Timing Switch; J. Y. Hartman, New Orleans, La. App. filed June 18, 1926.

1,669,318. Electrical Appliance; C. C. Baad, Bronx, N. Y. App. filed June 19, 1926. A table lamp having a base within which a pair of electrical appliances are normally housed, but which may be moved to an exposed position for use by dropping suitable doors provided in the base.

1,669,334. Coil Casing and Switch Therefor; W. Hemingway, Jr., Vicksburg, Miss. App. filed March 1, 1923.

1,669,337. Live-Line Clamp; G. A. Iler, Youngstown, Ohio. App. filed Sept. 30, 1925.

1,669,372. Multiple-Series Switch; V. R. Despard, Valparaiso, Ind. App. filed Oct. 16, 1925.

1,669,373. Operating Means for Rotary Switches; V. R. Despard and H. C. R. Popp, Valparaiso, Ind. App. filed Oct. 16, 1925.

1,669,374. Rotary Snap Switch; V. R. Despard, Valparaiso, Ind. App. filed April 9, 1926.

1,669,385. Method of Producing Electrical Heating Elements; E. L. Wiegand, Dormont Borough, and A. P. Wiegand, Crafton, Pa. App. filed June 4, 1927.

1,669,386. Safety Control Device; W. W. Williams, Bloomington, Ill. App. filed Dec. 12, 1925. For a liquid fuel heating system.

1,669,393. Battery Solution; A. Dembowick, Minneapolis, Minn. App. filed Aug. 4, 1926.

1,669,400. Impedance Meter; C. E. Vawter, Philadelphia, Pa. App. filed Aug. 5, 1921.

(Issued May 15, 1928)

Reissue 16,966. Synchronizing Device; O. C. Traver, Schenectady, N. Y. App. filed July 29, 1922. Automatic.

Reissue 16,967. Induction Furnace Having Unidirectional Circulation; J. R. Wyatt, Camden, N. J. App. filed Aug. 29, 1928.

1,669,409. Sheath for Cable Connections to Electric-Iron Plugs; G. Browning, Wilmette, Ill. App. filed May 6, 1926.

1,669,434. Switching Device; G. Werner, Frankfort-on-the-Main, Germany. App. filed May 17, 1924. For the electrical connection in any desired combination of a plurality of points of electrical operation.

1,669,447. Conduit Fitting; J. C. Boyton, Cleveland, and W. H. Doddridge, Lakewood, Ohio. App. filed Jan. 2, 1926.

1,669,453. Wiring System for Transformers for Multiphase Furnaces; H. Brock, Knapsack, near Cologne, Germany. App. filed March 15, 1927.

1,669,468. Medical Electrical Apparatus; C. Heintze, Chicago, Ill. App. filed Jan. 28, 1926. For electric ray treatment.

1,669,478. Lighting Fixture; J. G. Lengel, Los Angeles, Calif. App. filed Jan. 24, 1927.

1,669,484. Therapeutic Apparatus; C. W. Mowry, Portsmouth, R. I. App. filed March 17, 1926.

1,669,493. Circuit Breaker; J. Slepian, Swissvale, Pa. App. filed Oct. 15, 1923. Air type.

1,669,494. Lightning Arrester; J. Slepian, Swissvale, Pa. App. filed April 29, 1924. For direct-current circuits.

1,669,505. Regulation System; L. N. Crichton, Wilkinsburg, Pa. App. filed July 6, 1923. For the transmission of power at high voltages over long distances.

1,669,507. Prime Mover and Clutch; J. T. Dickson, Los Angeles, Calif. App. filed Feb. 11, 1927.

1,669,509. Electric Controller Device for Signals; S. J. Eyrse, Minneapolis, Minn. App. filed Dec. 17, 1924.

---

Information on foreign patents can be obtained through the nearest district office of the Bureau of Foreign and Domestic Commerce, Department of Commerce.

# New Trade Literature

INSULATING VARNISH.—The John C. Dolph Company, Newark, N. J., is distributing a solvent and calculating chart for Dolph's insulating varnishes.

CONTROL EQUIPMENT. — Bulletins GEA-19D, GEA-252A and GEA-360B issued by the General Electric Company, Schenectady, N. Y., describe and illustrate respectively its CR7006-D4 and D5 alternating-current inclosed magnetic switches; the type M, multiple unit control system for railway service, and the CR7761-F1 remote-indicating speed controller for slip-ring induction motors. The company also is distributing the following bulletins: GEA-468A, covering drum-type controllers for direct-current adjustable-speed motors; GEA-743A, describing drum controllers for two or three-phase slip-ring induction motors, and GEA-980, covering inclosed speed-regulating rheostats for starting and field control of direct-current motors.

ELECTRIC WATER HEATERS.—The Automatic Electric Heater Company, Philadelphia, has issued bulletin No. 51-28 covering the "Sepco" low wattage, storage type, electric water heaters. A diagram shows the construction of the heater, and operating data are included in the bulletin.

STREET-LIGHTING EQUIPMENT.—"Overhead Street Lighting Equipment" and "Ornamental Street Lighting" are the titles of catalog 218-A and 218-B issued by the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa. These catalogs give complete information on all street-lighting equipment and accessories manufactured by the company, and also describe and illustrate the equipment with photographs, dimensioned line drawings, charts, and line drawings. New equipment and improvements on former designs are also included.

LIVE LINE MAINTENANCE TOOLS.—Catalog No. 4 issued by the Tip's Tool Company, Inc., 325 East Main Cross Street, Taylorville, Ill., covers a complete set of Tip's tools for live line maintenance. An illustration shows the practical application of the company's No. 11 live line maintenance guard and a drawing shows the method of working double circuit lines. Other illustrations show the method employed in using various tools.

ELECTRIC MOTORS.—Bulletin No. 102 issued by the American Electric Motor Company, Cedarburg, Wis., covers the American two and three-phase induction motors from ½ hp. to 200 hp. The bulletin contains an illustrated general description of the various types, gives the advantages of each and details the methods of manufacture.

SWITCHING EQUIPMENT. — Bulletins GEA-14B, GEA-53B and GEA-931 issued by the General Electric Company, Schenectady, N. Y., describe and illustrate respectively its automatic switching equipment for sectionalizing and reclosing service; busbar clamps and clamp terminals for outdoor switching equipment, and automatic switching equipment for alternating-current railway-signal and train-control feeders. Bulletin GEA-974 issued by the company gives the dimensions of its type FKR-55 oil circuit breakers.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered, further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number:

Purchase is desired in Cape Haitien, Haiti (No. 31,433), of motors and generators.

An agency is desired in Copenhagen, Denmark (No. 31,390), for electric refrigerators.

Purchase and agency are desired in Constantza, Rumania (No. 31,449), for dental X-ray apparatus.

---

Any manufacturer desiring to establish agencies abroad may consult with the nearest district office of the Bureau of Foreign and Domestic Commerce, Department of Commerce, where data on available agencies throughout the world are on file.

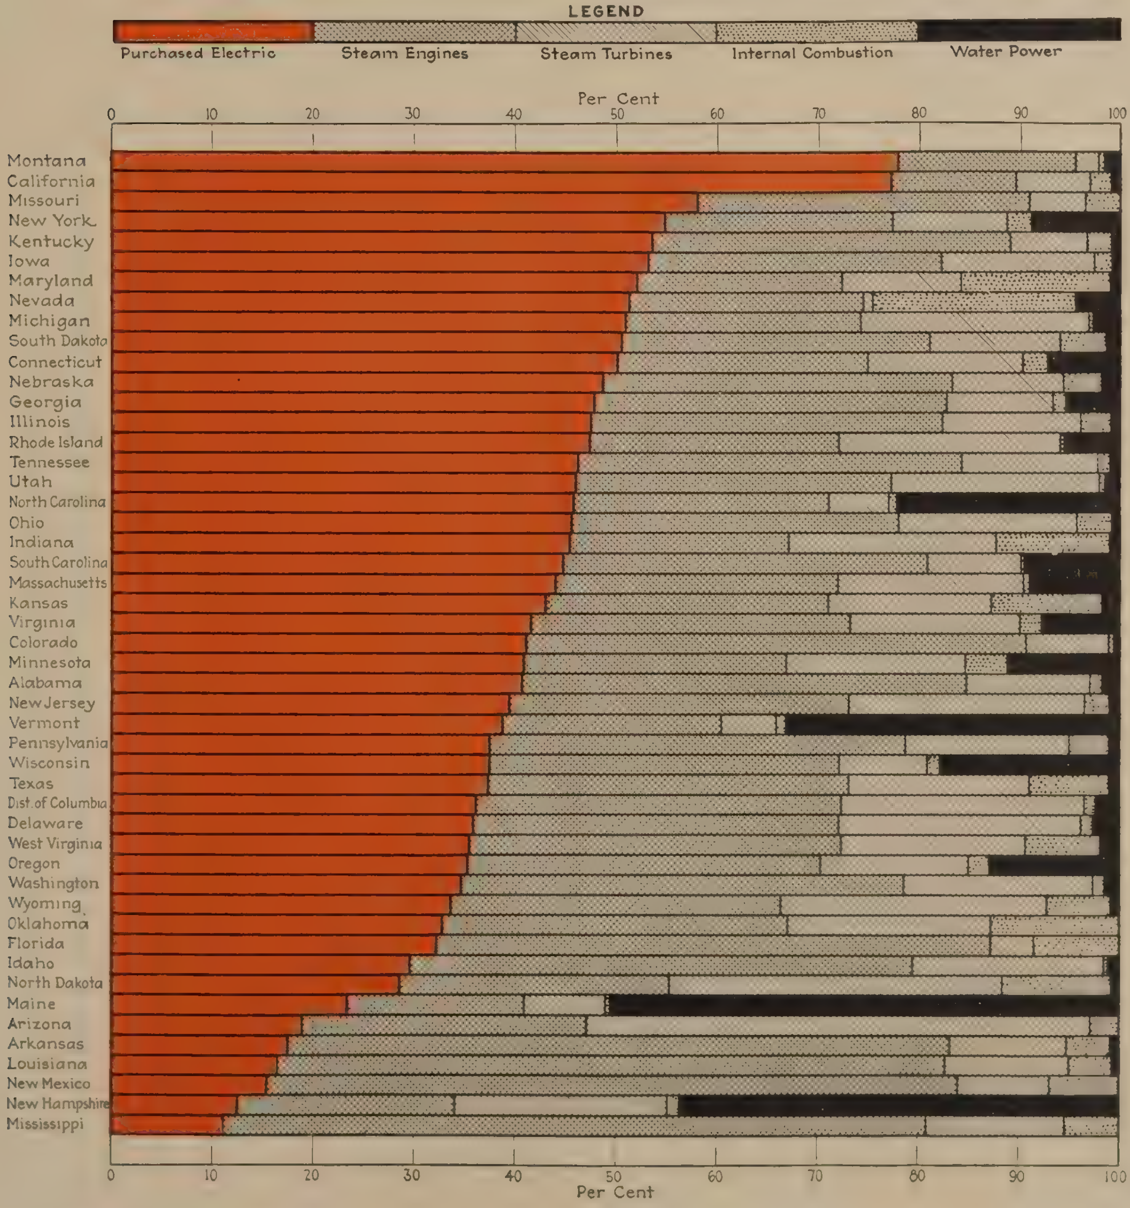
# Business Facts for Electrical Men

Selected Statistics Presented Graphically for
the Use of All Interested in Analyzing the
Trend of the Electrical Business

## Where Is the Industrial Power Market?

In Montana 78 per cent of the installed horsepower used in manufacturing is comprised in motors operated on purchased electric energy. In Mississippi it is only 11 per cent. The remainder uses steam, internal combustion engines and water power. Electrical operation on energy generated within the establishments is not included. The chart is based on the 1925 census of manufactures.

SOURCES OF POWER IN MANUFACTURING IN THE UNITED STATES



# Southern Operations Slightly Below Those of Last Year

| All industry (United States) | 119.3 | 118.2 | 116.9 | 120.9 | 116.5 |

April witnessed a more or less seasonal drop in industrial operations in the Southern States. The April rate of production was 2.7 per cent under March. Past history indicates that such a rate of decreased industrial operation would be expected at this season of the year. The average rate of general production during the first four months of the current year is about 1 per cent under the same period of 1927, a remarkable tribute to the industrial development of the South when it is remembered that the average rate of operation in the textile plants of the South so far this year was 14 per cent under the same period last year. General industry in the nation as a whole reported an April activity of 0.9 per cent above March and about 2.2 per cent above April last year. The textile and paper and pulp industrial groups were the only two reporting April operations under those of last year.

# The N.E.L.A. Convention in Perspective

THERE was a great gathering of public utility executives at Atlantic City this week. Leading men came from all sections of the country seeking information and advice. They had heard rumblings of the investigation being conducted by the Federal Trade Commission and had read garbled reports of the doings of state committees on public utility information. What was to be the answer of the electric light and power companies of the country to these accusations and insinuations? Was the industry to be damned by distorted publicity and remain dumb?

From the beginning to the end of the convention the answer to these questions was forthcoming. The National Electric Light Association, through its president, its public policy committee and its chief executives, spoke. The industry found its tongue and gave voice to its policy on public information. It announced from the housetops that it will use all proper channels for the diffusion of information concerning the electric light and power business. It accepted full responsibility, openly avowed, for its every word and act. It asked only that it be not condemned merely for speaking at all, or told that it has no right to defend itself in the press or to protest against false statements in the schools. It is willing that its own declarations be disregarded along with intemperate criticism leveled at it, and that it be judged alone by its proved accomplishments and indisputable acts. On these, it declared, public praise or condemnation must be based.

THIS was the note struck at the convention that rang above all others. But there were many more. In this issue of the Electrical World is printed the articulate evidence that the light and power industry is going forward rapidly and is setting still higher standards for all its activities. It is improving its service through the development of the art, the perfection of its organization and the expansion of its facilities. The announcement that it has contributed $3,000,000 to the National Research Council program shows how it cooperates in well-considered plans for public benefit. Many able addresses traced the evolution of industry and showed how the investment and holding company is a logical agency for the conduct of utility business which has for its ultimate object better and cheaper service.

In all the meetings there was evidence of intense interest in every possible method to make the electrical industry more efficient. The commercial men have made positive strides in their work. They have a national sales program, a national sales policy which calls for co-operation, a national selling platform which has tangible planks on credit, advertising and sales prices, and in addition a balance-sheet policy which measures costs and returns. The engineers are trying to get more efficiency in capital expenditures and are using more foresight in system building. The accountants are becoming executive aids, and the public relations committees are trying to carry out tangible projects which will develop a nation-wide conception of the advantages of electric service and give the public a knowledge of utility affairs. No one can read the record presented in this issue without getting to know an industry which is wide-awake, busy, progressive and alert to every opportunity to adapt itself better to national service; but one must have mingled with the eight thousand electrical men at Atlantic City to get the inspiration, enthusiasm and spiritual values that vitalize the light and power industry of today.

VIEWING the convention in perspective, tracing its growth and conduct, and weighing comments of those who attended it, lead to constructive suggestions for future meetings. The exhibits are found to be a vital part of the convention activities and have become a major objective for many attending. But the convention programs might well develop along lines which would provide more opportunity for utility leaders to tell the rank and file how they are building the industry and in what respects the rank and file can carry out their plans. This would give unity in industry thought and action. There was some comment to the effect that too many papers dealt in self-praise of the industry on the one hand and in fault-finding with the public on the other. It was also remarked that many addresses contained facts and enunciated principles that would be new to a public audience but were well known to utility men. Thus it might be well to devote somewhat less time to so-called publicity-value program material and more time to basic plans for utility progress of a type to instruct and interest the thousands of utility men who attend the meetings. Every year sees a better convention than the preceding one, however, and the lessons learned at this year's convention will afford opportunity to make an even better meeting next year. In the final analysis, the fifty-first convention will mark a milestone in utility progress because it recorded new conceptions of how to win public confidence and demonstrated beyond cavil that the utilities have courageous and far-sighted leaders.

## *Puget Sound Company Wins Coveted Coffin Award*

AWARD of the Coffin medal and prize to the Puget Sound Power & Light Company of Seattle may have surprised many, because the municipal plant of Seattle is being constantly held up to public gaze as a wonderful example of the efficiency of local government in the electric light and power business. However, the record discloses that the Puget Sound company, while it may not have basked in the limelight of publicity, has been busily at work along original lines and particularly active in the farming communities surrounding the metropolis of the Pacific Northwest.

Electricity on the farm is being talked of in many sections; but in the State of Washington it has been made more than a topic of conversation—it is, in fact, a reality. To be sure, conditions on the Pacific Coast are such as to call for much irrigation and pumping of water; but the electric light and power companies of that section have been quick to translate that need into opportunity for rural electrical development and prosperity, and in that respect they are to be congratulated.

Another development of which the Puget Sound company has a right to be proud and which other companies might emulate with profit is the range load which it has succeeded in connecting to its lines. Every heating load from the flatiron up is a sizable load, and although it may entail a low energy rate, if properly developed the range business will be found profitable to the utility and a source of satisfaction to the user. Stone & Webster and the local management at Seattle are to be felicitated on capturing this year the coveted Coffin award. It will, we are confident, spur the company to still greater endeavor and mayhap to the vanquishment of municipal operation in Seattle.

* * * *

## *Sanity in Competition*

TRUSTS and monopolies have been outlawed for more than thirty years by government as repugnant to the fundamental philosophy of a democratic civilization. Government sought to build a large number of industrial units each standing alone and in competition with all other units. Yet economic conditions have developed so rapidly that a rigid adherence to such a philosophy of business cannot be other than a destructive policy, and after much floundering about there is evidence that modern business can be co-operative and yet remain competitive.

This is the day of mass production and distribution. There is competition between groups of industries and between industries. Hand-to-mouth buying is here, as well as modern facilities in banking, communication and transportation. Under the old-time conception of business competition, wherein each individual competitor stands alone, without group credit, market information or data on his group business, he finds himself driven to destructive competition in order to exist. He must seek relief through co-operation. Relief is had by the organization of business groups which pool individual interests and develop a workable machinery for co-operation in competition under the impulse of economic necessities and the guidance of governmental agencies. These groups may be called trade associations, business institutes or other names new to industry, but all operate on the same basic principles.

General Lincoln C. Andrews recently stated these principles as follows: "To promote in the industry a mutual confidence and high standard of business ethics; to eliminate trade abuses; to promote sound economic business customs and practices; to foster wholesome competition; to provide, for individual efficient business management operating independently, an opportunity to do business with an adequate return, and thus generally to promote the service of the industry to the public welfare." If business adheres to these principles in the formation of the mechanisms to give co-operation in competition, there is no doubt of the results. The sea is yet uncharted, but the beacon lights are installed.

* * * *

## *Accused, but Not Guilty!*

WISDOM, vision and the courage to face a difficult and critical situation characterized the utility men who journeyed to Atlantic City this week. Each had local conceptions and methods of thought as a result of some lack of public understanding of the utility business and of recent tendencies in the relations of government to all business. The national business trend toward consolidation, the attempts to get the government into business, the Federal Trade Commission's investigation of the utilities—these united to bring to a climax agitation over public relations both local and national. Utility men came from far and near to counsel together, to offer suggestions, to get suggestions and to prepare plans. They were accused, but not guilty; they had a policy, but not a method, and they wished to guide their local and national business into channels that would bear them toward greater and better electric service.

The light and power industry has an educational problem and must analyze more carefully the thoughts and emotions of the men and women of America. In his address President Sands said: "I have an abiding faith in the integrity and the ability of the American public to deal fairly with our industry once it is possessed of the requisite information for the exercise of intelligent action and the formulation of sound judgment. If we, because of adverse criticism, indifference or for any reason whatsoever, fail to see to it that the public has such information, then we must not blame the public if at times it fails to accord us that measure of justice to which we feel we are entitled." This is the counsel of wisdom and courage.

The industry has learned that public confidence cannot be obtained by passing its public relations responsibilities over entirely to undirected publicity departments. It has learned that good-will advertising can degenerate into braggart advertising very readily. It has learned that organized national good-will efforts must be planned carefully lest they grow into agencies which serve as the permanent repositories of job-holding men without vision. It has learned that the public responds slowly to protestations of virtue and rapidly to proofs of service. The industry has shown the customary human traits of selfishness, inconsistency, egotism and pride of accomplishment and has learned wisdom through these mistakes of omission and commission. Fortunate indeed is the electrical industry that its inexperience in dealing with human values has not led it into serious errors and mazes without exits. At this critical stage of its development it has knowledge gained through experience.

"Public relations" is only a catch phrase to express the desire to have the public believe in electric service and in those responsible for giving electric service with the same degree of faith that has led men of the industry to devote their talents and money to rendering this service. It takes faith, confidence, loyalty and enthusiasm to make both good business and good public relations. In business, as in everyday human relations, it is the unobtrusive, friendly and sincere carrying out of an unselfish service program that makes for happiness as well as prosperity.

* * * *

## *Commercial Program Crystallized*

FROM the commercial point of view the year just closed has brought significant progress that should encourage and stimulate the men of the sales branch of the power industry. There has been cumulative evidence that commercial purpose is crystallizing in executive thinking. The need for market development has long been discussed in theory. It is now taking more definite shape in a demand for action and the more serious consideration of the need for a balanced program that will evaluate the sales possibilities and the economies of the different classes of load. It might be said that the industry has been for some time groping and fumbling for commercial purpose. Now comes a demand for action.

Attention is focused particularly on the inadequacy of the electrical equipment of the home. Manufacturers, jobbers, contractors and dealers as well as power companies have been coming together in their thinking around this issue. Out of it has come a new spirit of mutuality, a more active desire for a practical co-operation which has expressed itself concretely first in the reorganization of the directorate of the Society for Electrical Development as a council of the industry and second in the calling of the Industry Sales Conference, now at work on the formulation of a broad sales program for the development of the popular market for electric service. President Sands and Commercial Section Chairman Davidson have given generous support and leadership to this movement, and its progress will stand as one of the achievements of this administration.

Impulse has been given to another policy of far-reaching commercial importance. This is an honest and sympathetic effort to effect closer co-ordination between the national associations of the industry. A very practical benefit has also come through the intertrade conference initiated by the merchandise committee with Mr. Greenwood as chairman. Out of this have come the definitions of a set of merchandising principles and standards that have done much to heal the widening breach between the power industry and the retail trades that sell electrical home-load appliances. This is constructive work that should carry forward steadily.

Broadly, action is indicated in four directions: A closer co-ordination of the organized industry for the purpose of going forward with the selling job, a practical attempt to define and reconcile the merchandising policies of the different sales agencies in industry, a more serious consideration of the need for better organization in the industry for sales work, and the growing realization that accurate cost accounting is essential to intelligent market operations. On top of this comes increasing opinion that the electrical industry must invest more money in market development and exert a stronger pressure of advertising in the "new competition." This point was stressed by Chairman Davidson and James H. McGraw before the convention.

It would appear that the period of commercial hesitation is finally at an end. The coming year should bring even more definite purpose and more decisive action in commercial affairs.

* * * *

## *Substations Passing Out*

LOAD growth in the electrical industry keeps engineers and system planners keyed to a high pitch. In larger cities a density is found ranging from 3,000 kilowatts to 300,000 kilowatts per square mile, and this density keeps on creeping upward. A ten-year perspective on load growth gives a new conception of a metropolitan system; it modifies present layouts and makes radical changes necessary.

The substation seems to be an expensive and hazardous incumbrance on the metropolitan system of the future which uses alternating current. It has served its time in the system layout and must pass, because it is no longer needed as a functional device. Instead of the substation there will be unit generators, an alternating-current grid distribution system, multiple-transformer vaults underground and synchronizing at the grid. It is a simple and reliable system, because all faults clear themselves if small cables are used to tap the network, no large concentration of energy is had in generating stations, system stability is a maximum and service is also a maximum owing to the simple layout and multiplicity of supply points. When several generating stations are used, there is no problem of tie cables or of load and wattless control. The system becomes the old Edison grid system, which has proved to be the most reliable system of supply and lacks only the storage battery to be comparable to the best direct-current supply system.

* * * *

## *New Jersey Public Service, Its Chief and Its Future*

THE dinner celebrating the twenty-fifth anniversary of the Public Service Corporation of New Jersey was as much a tribute to its organizer and president, Thomas N. McCarter, as it was to the company. Few executives have been in harness as long or have contended with as many discouragements and disappointments. And yet obstacles apparently served to sharpen his aggressiveness and quicken his zeal; for out of it all Mr. McCarter rises triumphant, with a splendid vision for the future of his corporation and of his state that is almost dazzling in its scope.

Mr. McCarter was Attorney-General of New Jersey when he was chosen to form and head the Public Service Corporation. Eminent as a lawyer, he was nevertheless handicapped at first in a field which at the time was primarily engineering in character. That he developed with the business and adapted his viewpoint to the expanding activities of his organization meant much for the public and the industries of New Jersey. Nor was his enterprise overlooked; for New Jersey responded and co-operated, with the result that the Public Service Corporation has in recent years grown by leaps and bounds. To Mr. McCarter's leadership most of the credit for this is due, and in his present state of optimism and justifiable pride of accomplishment there is no task in aid of the further development of New Jersey to which the Public Service Corporation and Thomas N. McCarter in particular will not set heart and hand.

*President Georgia Power Company*

# *Newly Elected President of the National Electric Light Association*

# Public Understanding the Keynote

Atlantic City convention notable success. Speakers dwell on social and economic aspects of utility service. Splendid business conditions reported. Exhibits attract thousands

MORE than eight thousand utility people and their friends met at Atlantic City on June 4 to 8 at the fifty-first convention of the National Electric Light Association. The meeting was another notable success in all respects—programs, exhibition, weather and attendance. It was a worthy addition to the great conventions held by the light and power industry in recent years, and the reports and addresses made at the meetings contributed greatly to its success.

Several major topics stood out as of primary interest at the meetings. The social and economic aspects of the utility business received great attention from the point of view of getting public understanding. The outstanding addresses of President H. T. Sands and other industry leaders were paired with notable addresses by leading bankers and industrialists. It was evident in these addresses that public understanding was a major problem to all business groups and that undivided executive attention was necessary to successful public relations.

An epoch of selling has been reached by the light and power industry, and many notable addresses and committee reports attested the fact that the industry is going to do its selling job. The entire program covered regulation, railroad electrification, finance, commercial aspects of utility business, engineering, accounting, public policy, insurance, employee relations and a host of other topics which show the complexity, magnitude and national influence of the companies embraced in the association.

The first meeting of the convention gave evidence of the high quality of the programs that followed. After a hearty welcome to Atlantic City by a local official President Sands delivered his address. He said that the industry had made consistent progress during the past year on such projects as research, interconnection, home service, economy in operations and rural electrification and that nothing indicated that the peak of development had been reached in the art or in the service rendered. He praised the work of the four national sections as being basic to industry progress and told of the good work done by the committees of the association.

A notable feature of his address dealt with the Federal Trade Commission's investigation. In logical and sane terms he dealt with the several aspects of the investigation and recorded his confidence in the integrity of the utility industry and in the ethics of its leaders. He presented the facts in regard to school relations, public utility information bureaus, financial expenditures and other matters which—by inference only in many cases—have been called propaganda activities. He asserted the need for public information and the obligation of the industry to furnish it. President Sands urged a sane perspective and expressed an unbounded faith in the industry, in its leaders and in the continuance of the public confidence it holds.

At this meeting Treasurer P. S. Young gave a report of N.E.L.A. finances and Chairman Howard K. Mohr reported good news concerning growth in membership in the association. Managing Director Paul S. Clapp, in an able address, recounted the developments in the industry, told of the work of the headquarters staff and gave a complete picture of the large number of activities in which the association is concerned. He asserted that the industry assumes responsibility for extending and improving electric service in America and at this time is making great progress in its efforts to bring electricity to the farms. He maintained that the size and prosperity of the industry made it a focal point of public opinion and that its work was the best evidence of the success with which it had carried out its responsibility for service.

*J. S. Wise, Jr., G. M. Gadsby, L. O. Ripley and R. H. Timmons*

In a ringing address J. F. Owens, chairman of the Public Relations National Section, dealt with the spiritual and service aspects of utility affairs. He declared that the signing of a contract was only half the service job and pointed out that all utility employees had an obligation to carry through to completion the broadest possible conception of service. He accented the need for telling the public about the utility business.

In an able paper A. W. Thompson, president of the United Gas Improvement Company, Philadelphia, presented the case of the investment company. He traced the economic growth of business, whereby it increased in complexity and size so that owner management was necessarily replaced by professional management and the pooling of finance and service resources. In his opinion the outstanding feature of the electrical industry was good management, and this intangible element had equal rank with the tangible assets of the industry. He then gave the well-understood basic values accruing to the use of holding-company operations in the utility business.

Radio and its importance as a load and as an operating facility was the topic of an able paper by H. P. Davis, chairman of board, National Broadcasting Company. He said that the advent of the alternating-current radio set makes possible a new and attractive load for utility lines and that radio broadcasting opened new approaches for utility executives to get public understanding.

A feature of this meeting was an announcement by R. F. Pack that a co-operative research project had been approved whereby $300,000 per year for ten years would be spent under N.E.L.A. auspices.

### As Others See Us

Addresses by Samuel M. Vauclain, president Baldwin Locomotive Works; Oswald W. Knauth, vice-president R. H. Macy & Company, and Henry G. Wells, president National Association of Railroad and Utilities Commissioners, were features of the Wednesday morning general session. From within the industry there were addresses by J. E. Davidson, chairman of the Commercial National Section, and Dr. Willis R. Whitney, General Electric Company, the first being a vigorous call to sales action and the second a general picture of how closely progress is tied up with scientific research. The rate research report by Edwin Gruhl had even more interest than in previous years because of its analysis of recent criticisms. Reports of the codes and standards committee by I. W. Day and the exhibition committee by E. W. Goldschmidt completed the program.

Mr. Vauclain, relating some history on which future prosperity will have to be built, announced that as far back as 1890 he specified individual electric drive throughout the Baldwin works. Despite this pioneering move, industry as a whole was only 4 per cent electrified ten years later. "Why do industrial plants continue to put in their own boilers and generating equipment when the total costs of power so developed will be from three to six times that of purchased power?" he asked. Mr. Vauclain expressed the opinion that it is folly to worry about displacement of common labor with machinery because we shall not have any common laborers, in the old sense, soon. He urged industries to listen to the suggestions of their younger men, convinced that their power of understanding is greater than that of the passing generation on account of increased facilities for education. The prophecy was made that all trunk-line railroads and 50-mile laterals on the Atlantic Coast from Boston to Washington will be electrified in the next ten years.

Mr. Knauth outlined several principles of good merchandising. These are affording varied but rapid selection, permitting returns within a reasonable period to maintain good will, adjusting sales force to periodic fluctuations in volume, and balancing turnover and selection. Difficulties imposed by utility merchandising methods were related. He expressed the opinion that utilities should leave merchandising to existing distribution channels and concentrate on expanding public consciousness of opportunities for using electric service.

Mr. Wells defended utilities against certain accusations but at the same time warned of impending trouble if certain practices are not avoided. For example, he said that the majority of the industry should exercise moral suasion on the minority to prevent bad practices. Utilities must assume the duties imposed by their privileges. Electric utilities have the right to be heard in newspapers, public schools and in Washington, he declared, the same as any industry when it is oppressed or misunderstood, but there must be no evasion or distortion of truth. Holding companies are justified, he declared, until they become mere stock-jobbing concerns that ignore the rights of subsidiaries and conceal profits. Considerable attention was given to what constitutes a fair basis for figuring returns and avoidance of delays in adjustments.

Mr. Gruhl contended that many criticisms of rates are so general or are based on such non-comparable circumstances that they cannot be answered. Furthermore, a failure to refute last year's analysis of rates implied ignorance or misrepresentation on the part of critics. He reported that analyses of the two recent criticisms of rates including "What Price Rates?" have been completed. Since 1926 there has been a reduction of nearly 3 per cent in the average domestic rates.

### Railroad Electrification Featured

On Wednesday afternoon a splendid program was presented which featured railroad electrification as one of the outstanding possibilities for further business growth. Britton I. Budd presented a report of the railroad electrification committee which contained complete statistical summary and digest of opinion as regards electrification in all parts of the world. Recent developments in this country pointed to a rapid increase in railway electrifications supplied from utility lines. President Lawrence A. Downs of the Illinois Central gave an excellent paper on this topic. He told of the reasons for and results of the Chicago electrification and predicted a big future for electrical operation. He urged greater standardization as a means to increase the growth and reduce costs.

John E. Edgerton, president of the National Association of Manufacturers, gave a fine talk on the relation of government and business. Politics, feeding on public indifference, was alleged to be largely responsible for bad trends in the relation of government to business, and he argued that no help could be had until this indifference had been dissipated. He observed that government had got into industry and business largely by invitation and that government takes advantage of industry group selfishness and quarreling.

Women are inquiring into government and into social and economic affairs, Miss Belle Sherwin, president of the National League of Women Voters, declared in a good address which outlined the methods used by the league to develop women's thoughts and acts on aspects of business.

*J. F. Owens*

*A. W. Thompson*

Newly elected vice-presidents of the National Electric Light Association

A feature of the meeting was the notable progress recorded in rural electrification during the year and an address by Clifford V. Gregory of the *Prairie Farmer* which discussed rural electrification from the farmer's point of view. He said that farmers were machinery-minded and desired electric service, and he outlined a method which he thought the best for doing work for rural electrification.

### Public Policy Meeting

On Wednesday evening the feature meeting of the convention was held. A large audience listened to masterly addresses by R. H. Ballard and Melvin A. Traylor, president First National Bank of Chicago; witnessed the Coffin award presentation to the Puget Sound Power & Light Company and was entertained by Richard Crooks, tenor, and B. A. Rolfe's orchestra.

R. H. Ballard, chairman of the public policy committee, gave an able address on public policy and presented the official statement of the National Electric Light Association about alleged propaganda and undue influence on schools and concerning other matters of public interest.

Mr. Ballard said the greater use of appliances in homes and increased efficiency in operation had made it possible for the industry to reduce rates to customers and yet improve service. He dealt at length with the Federal Trade Commission's investigation and showed how the utility industry had followed economic trends of today to better and cheaper service and had used every logical method to tell the public about its business. The industry rightly has taken steps to defend itself against attacks of a group whose every act indicates a lack of practical knowledge in business affairs and whose guiding thought is political rather than economic. Certain proposed governmental projects involving the power business and built upon unsound economic ideas were also combated by the men who had made a specialty of public service. The record of the industry in service and achievements was held out as proof of ability. Mr. Ballard said that a duty rested upon the industry to make its affairs known to the people and to advise them about matters of industry concern.

*S. Z. Mitchell, B. I. Budd and F. L. Dame*

The social and economic aspects of the utility industry were dwelt upon by Mr. Traylor, who made a summary of economic evolution in business, stated the needs of modern business and dealt with the social relations and obligations involved in the conduct of big affairs.

### Education and Water Power

On Thursday morning several papers dealing with education were presented. Dean C. O. Ruggles of the College of Commerce, Ohio State University, gave an outline of a survey under way to evaluate industry needs in man power and the ability of the schools to impart the necessary instruction. Deane W. Malott, assistant dean Harvard Graduate School of Business Administration, said business had become a professional occupation and that the professional business schools were needed. He said these schools must work closely and intimately with industry to get the best results.

At this meeting Paul A. Schoellkopf presented an excellent report on water-power development which was replete with statistical data and contained an admirable summary of industry ideas on this subject. Franklin T. Griffith strikingly discussed private business and government business relations and stressed the imperative need of private initiative and research in the utility business if advances in service are to be recorded.

It was taken for granted that the lamp committee report presented by Chairman Frank W. Smith would be another notable addition to the fine reports this committee has prepared in the past. The data on lamp production, lamp voltages and lamp sales and a discussion of the business aspects of the subject gave an encouraging aspect to the lamp situation. At this meeting also W. H. Onken, Jr., gave the N.E.L.A. prize awards committee report. The prize winners are recorded elsewhere in the issue. Mr. Onken reported that an unusually good list of papers had been submitted.

### Teamwork and Co-operation

On Thursday afternoon reports and addresses of much merit were presented. Fred R. Jenkins told of the notable accomplishments of the educational work with employees. W. W. Freeman gave an address devoted to the value of teamwork in utility progress. He pointed out the interrelations in the utility business, the possibilities for more and better service, the dependence of the utility industry upon other industries for prosperity, and gave in all a striking picture of what teamwork would accomplish.

Breadth of vision and a tangible conception of the need for and value of well-developed commerical aviation facilities characterized an able address by William P. MacCracken, Jr., Assistant Secretary of Commerce, Washington, on commercial aëronautics. Progress in this direction has been rapid in this country, but business in general has not supported commercial aëronautics sufficiently or realized the service it can render, he said. A development program should receive the hearty support of all business.

Labor's part in electrical development was the topic of an address by Hugh Frayne of the American Federation of Labor. American labor has done wonders to enhance its status through its own efforts and through its foresight in adapting its program to the evolutionary advances in modern science and industry, Mr. Frayne asserted. As never before, labor is using its head as well as its hands, and it seeks to use power, mechanical production methods and other developments so that economic benefits both to the country and for labor will result.

In a fine address Merle Thorpe, editor of the *Nation's Business,* dwelt on human and governmental relations in business. Paternalism is the American brand of socialism and is the real foe of our democratic institutions today, he declared. Paternalism breeds bureaucracy, and bureaucracy is a greater menace today than communism or autocracy. Paternalism now looks for new worlds to invade and has assumed two phases—alleged governmental service and government operation of business. The spearhead is leveled at the public utilities. Paternalism would produce and distribute power and light. It would manufacture and sell fertilizer. It would market the farmer's grain and hogs. It would operate the merchant marine. The electrical industry is today carrying its brunt of the attack. If the bureaucrats are successful, they will then turn their attention to the canners and bankers and steelmakers. The present attack on the utilities is a signpost marked "detour." It would take us down an uncharted road with uncertain destination, harassed by bureaucracy, denying us a continued higher standard of living and our destiny of economic freedom.

A thoughtful address on the evolution of business was delivered by John T. Madden, dean of the School of Commerce, New York University. He traced the growth toward consolidation and pointed out the economic pressures that have resulted in the use of investment companies as a means to conduct big business under present conditions.

The final meeting on Friday morning was marked by two addresses of much interest. Interconnection freed from "bunk" was the topic of George N. Tidd, president American Gas & Electric Company. He deplored much of the publicity given the non-essentials of interconnection and pointed to the need for telling the public in tangible terms how interconnection benefits service.

The other address was by James H. McGraw, president McGraw-Hill Publishing Company, Inc. Mr. McGraw discussed industry selling and stated that the major principles which should be applied were the quality of the product, its presentation and its price. In the modern business world, he said, competition between industry groups made it necessary to study selling problems as never before, and he urged the electric industry to take its proper position in the marketplace.

Constructive talks by Arthur Williams, chairman of the insurance committee, and John F. Gilchrist, who gave a very helpful address on electrical advertising, were added features of the final session.

### FOUR SECTIONS ACTIVE

On Tuesday afternoon the four national sections held their meetings, and each attracted a large and interested audience. The committee reports were all records of industry stability and progress, and addresses of high merit added to the value of the meetings.

At the Public Relations Section meeting Chairman J. F. Owens urged the necessity for all utility people to help in getting the public to understand the utility business. That his admonition is being put into tangible form was attested by the splendid series of reports presented at the meeting. Feature addresses were those of Clayton Rand, president Dixie Press, Gulfport, Miss., entitled "Thunder and Lighting," and Mrs. Anne Steese Richardson, *Woman's Home Companion,* entitled "Women's Place is in the Home." Both speakers dwelt on human values and with wisdom and humor gave inspiring suggestions which could be applied to public relations work.

### ACCOUNTANTS AID MANAGEMENT

To any one whose last glimpse of an N.E.L.A. Accounting Section meeting was ten to fifteen years ago the attendance at this year's session was a great surprise. The "Rose Room" of the Traymore, in which seats for approximately 300 were provided, was completely filled. Long technical committee reports have been discontinued, as in the other sections, by presenting serial reports throughout the year, and there is a trend toward bringing in viewpoints of other than utility accountants. One paper was presented by Charles B. Scott, president Bureau of Safety, Chicago, on "Insurance Costs." He emphasized the possibilities of economy by comparing losses and premiums, making structural changes and analyzing personnel according to risks. His paper is abstracted elsewhere in this issue.

An inspirational address was delivered by Earle W. Hodges of Henry L. Doherty & Company on "Common Sense and Dollars." A discussion on "Accounting Treatment of Securities Discount and Expense" was given by Prof. David Himmelblau of Northwestern University, and in it some rather unorthodox suggestions were made.

E. W. Lloyd, vice-president Commonwealth Edison Company, emphasized an outstanding problem for which accountants must find the solution if utilities are to continue stimulation of energy usage through merchandising and new-business activities and not be penalized for expenses which are not truly merchandising or commercial. He referred particularly to the disposition of expenses for promoting pioneer uses of electricity, such as electric heat applications and devices which have not received general public acceptance. Allocations of expenses for transportation, rent, advertising, servicing, etc., connected with merchandising and new business are also not equitable, he declared. His contention was that some expenses are not truly merchandising expenses and should be chargeable to electricity sales. A more complete report of his address is presented elsewhere.

E. A. Davis, Accounting Section chairman, in opening the session, pointed out that growth of business and government requirements have imposed a burden on accounting departments that has not been relieved by increased personnel. He urged greater dispatch in organizing committee activities each year, avoidance of let-up in activities around March, and organization and training of accounting personnel for promotion through succession.

*W. H. Onken, Jr., R. H. Ballard, Marshall Sampsell and M. J. Insull*

H. C. Hasbrouck pointed out that the N.E.L.A. classification of accounts has been adopted by 29 state commissions and is favored by four more. For next year he recommended co-operation with the Commercial Section on merchandise and jobbing accounts and standardization of interconnection agreements. B. F. McGuire reported great development in machine accounting that has simplified operations and reduced unit costs. J. E. Loiseau announced that two reports on corporate finance—investment surplus and mortgage provisions—had been submitted and reported that work had been started on the latest tendencies.

M. R. Scharff declared that excellent results on studies of fixed-capital accounting had been obtained by assigning different phases to geographic divisions and recommended studies of additions to leased companies, periodic audits, improvement budgets and joint-pole construction. E. J. Brett recommended discontinuance of the general records committee. W. G. Young referred to three serial reports on purchasing and storeroom accounts. R. G. Smith announced that the summary of 1927 statistics from more than 300 utilities are now available.

The engineers of the industry at their meeting dealt with the economic aspects of the utility business. They presented a planned program for research, for system building, for standardization and for expenditures whereby their new slogan of "More capacity per dollar of investment" would have a tangible result.

The work of the year was outlined briefly by E. C. Stone, chairman of the National Section, and the attendants then listened to three able addresses. Alex D. Bailey stressed the importance of engineering research in utility progress. He noted the research work done in this country by several organizations and in conclusion stressed the point that the N.E.L.A. itself should embark upon a research program if it hoped to achieve the best results quickly.

W. E. Mitchell, vice-president Georgia Power Company, addressed the Engineering Section session on Tuesday afternoon. His subject was "Spending Our Company's Money," but Mr. Mitchell confessed to the "hobby of making human beings out of engineers," stating that any one could tell you how to spend money.

The opportunities for advancement and the type of progressive engineering thinking conducive to successful activities in this field were pointed out by Mr. Mitchell. The problems of a broad engineering viewpoint involving the increase of industrial productivity through scientific developments and a sense of engineering costs were considered as essentials. Mr. Mitchell urged not only the development of young engineers for utility work in the "school of hard knocks," but also the development of the abilities of men already in the organization.

The field of management was that suggested by Mr. Mitchell as offering the greatest promise. He urged young engineers to "broaden your field, lift your eyes, prepare for opportunities, eat up all the responsibilities in sight."

Chairman Stone also spoke on engineering planning and dealt at length with the complete meaning of economy in system planning. The engineer has a responsibility second to none in the industry, he said, and must measure up to the new economic conditions faced by it.

*A group of electrical men, including P. S. Arkwright, W. A. Taylor and H. P. Liversidge*

The Commercial Section closed its year's work with the announcement of many fine achievements. Outstanding was the final approval by the public policy committee of the interstate agreement on appliance merchandising. This has been a splendid achievement by the merchandising committee under the leadership of E. R. Greenwood, resulting in the adoption of certain merchandising principles by the power industry and the various associations of retail dealers who sell electrical household appliances. The merchandising committee also announced that 159 central station companies have entered the one-more-kilowatt-hour-per-day contest.

S. N. Holliday of the General Outdoor Advertising Company pictured the waiting opportunity for the upbuilding of the sign load and declared a potential business of $200,000,000 a year in prospect. M. C. Huse reported for the wiring committee, outlining the plans for co-ordination with the coming program of the Industry Sales Conference and commenting on the state of code development. H. W. Derry presented the report of the power committee in the form of a chart talk picturing the field for further development of motor load. W. H. Sammis exhibited two reels of a moving picture of electric heat in industry.

*J. F. Owens, W. E. Mitchell, A. M. Perry and President H. T. Sands*

Starting with the reception to President and Mrs. Sands on Monday night and reaching a climax at the ball on Wednesday night, the social and entertainment features of the convention maintained the high standards of previous years. The ladies came to the meeting in large numbers, and dances, teas, trips, golfing and other pursuits afforded pleasure in ample amount. Dancing on the pier was the evening attraction of greatest drawing power.

### Exhibits Better Than Ever

Serious interest in the exhibits well repaid the manufacturers in presenting a splendid display of new appliances and apparatus. That progress in the industry still goes on apace became self-evident after viewing the material on display. Despite the mechanical nature of the equipment, year after year the show is being made more beautiful and artistic in appearance.

Manufacturers who exhibited did not show a mass of equipment but confined their display to new developments. There were 209 companies participating. This means that 53 per cent of the manufacturer members took part, and, because of the lack of available display space, a few were unable to obtain booths. There was a 7 per cent increase in exhibits, since in 1927 194 manufacturers took part. From 41 participating companies in 1908 to 209 in 1928 is the colossal achievement in a display which now includes the most modern electrical appliances and power-house and distribution equipment.

# President Sands' Address

Work of the year discussed
Discussion of Federal Trade Commission investigation
Comments on committee activities

H. T. Sands

THE past year has witnessed a continuation of that consistent progress which has been the record of our industry from its inception. Intensive research conducted by our engineers is continually bringing to light new methods and economies in the production and use of electrical energy. Turbines with capacities and efficiencies hitherto unknown have been displaced by those of still greater capacity and efficiency.

High-voltage transmission and interconnection have gone on apace, bringing to the smaller communities electric service of the same character furnished to the large cities. There is a distinct trend toward decentralization of industry, due to the ability of smaller communities to offer to industry dependable electric service at reasonab'e cost. The home has been made a much more livable institution and the burden of the housewife greatly lightened through the introduction of the many domestic appliances which have demonstrated their worth. During the year 1927 one and one-quarter million homes were furnished with electric service for the first time.

Electric service on the farm has become a practical reality. Some four hundred thousand farms are now receiving electric light and power company service, and the farmer and his family are enjoying a standard of living and comfort hitherto unknown through the many profitable applications of electricity to farm homes and farm work. Mass production has reduced the cost of generation and the public has received benefits therefrom. Today electric service is being furnished over wider areas and at a lower cost per unit to the consumer than ever before.

Our service touches intimately the industrial and social life of the entire country and affects both the comfort and the economic welfare of every individual in the nation. This imposes on the industry an obligation of service of which it is keenly conscious and which it is anxious to discharge to the utmost of its ability. What the future may bring no one can foretell; but the record of the past justifies the belief that in the development of the art we have by no means reached the peak—that new inventions and discoveries will make possible a still more extended use of electric service and at a lowered cost to the consumer. As in the past, each step in future development will bring with it its own peculiar problems. The industry faces the future confident of its ability to solve these problems as they arise in the interests of all concerned and to continue to render to the public a good account of its stewardship.

As in past years, the major portion of the activities of the association during the present administrative year have been conducted through the several committees of the four national sections — Accounting, Commercial, Engineering and Public Relations. The interim reports published during the year and those to be presented to the convention by the chairmen of these four national sections present a fairly complete picture of the year's accomplishments. It is my purpose, therefore, to consider only some of the outstanding activities undertaken by these national sections, to touch briefly on some phases of the work of some of the other national committees and make some observations in respect of some present-day matters that I deem should receive the careful consideration of the members of the association.

## *Accounting National Section*

IN CARRYING on the work of its several committees, the Accounting National Section has placed added emphasis on the importance of geographic committee organization, co-ordinated with the committee organization of the national section. Much attention has been given to the public relations aspect of the work of the accountants in our industry and to the importance of the accountant viewing the conduct of his departmental activities in the light of its effect not only on the accuracy of the companies' records but also on the companies' relations with the public.

The section has also had clearly in mind the desirability of the trained accountant executive, believing that more and more the industry will require executives with a thorough groundwork of accounting experience.

This objective brings to the work of the several committees a wider perspective and to the accountants in our industry a broader outlook. The accounting department is the compass by which the managing executive establishes his position and determines the future course to be followed.

## Commercial National Section

AT THE request of the executive committee of the Commercial National Section, and with the approval of the national executive committee and the public policy committee, a commercial director has been engaged and is now attached to the headquarters staff. The association is particularly fortunate in having secured for this position C. E. Greenwood, for many years in charge of the commercial department of the Edison Electric Illuminating Company of Boston. Mr. Greenwood brings to this office a long experience in the commercial activities of the association and is particularly qualified to fill this most important position.

Another new activity undertaken under the auspices of this section resulted in the establishment of a service in home economics available to colleges and teachers. Miss Eloise Davison, professor of home economics in Iowa State College, has been engaged for this work. Her services are available to colleges and universities throughout the country. The requests already made upon the association for these services demonstrate the worth of this new activity.

In building for better and more aggressive merchandising practices, the section has stressed the importance of having high-grade executives at the head of the commercial departments of the operating companies—executives who will measure up to the sales executive in other lines of business.

Under the auspices of the merchandising committee several meetings have been held with representatives of other lines of business engaged in the sale of electrical appliances. Out of these conferences has come a realization of mutual interest and a better understanding of one another's problems. A set of merchandising principles has been drawn up and subscribed to by the various interests represented in these conferences.

## Engineering National Section

THE Engineering National Section adopted as one of its major aims in this year's work "more system capacity per dollar of investment." To this end the section has effectively co-operated with manufacturers of apparatus and equipment for more extensive standardization. Much work has been done and excellent results have been accomplished in co-ordinating the research work carried on by the several branches of the electrical industry.

The accident prevention committee, in collaboration with committees of the American Gas Association, American National Red Cross, American Telephone & Telegraph Company, Bethlehem Steel Corporation, United States Army and Navy, United States Bureau of Mines, United States Bureau of Standards and United States Public Health Service, has prepared and published a "Manual for First Aid and Resuscitation" for use by employees in case of electric shock, asphyxiation or drowning. This manual should be in the hands of every employee.

I wish to speak in particular of the excellent and constructive work which continues to be done by the inductive co-ordination committee. I question if the importance of this work is fully appreciated. In spite of the increased inductive influence from new high-voltage construction and larger loads on distribution feeders and the increased sensitivity of communication circuits, expansion in facilities has taken place with a minimum of conflict with those in charge of communication interests.

This development has taken place on the basis of engineering treatment, without the enormous burden of expense that might have been entailed in legal disputes. It represents a co-operative effort in American business of the highest order.

## Public Relations National Section

PURSUANT to resolution adopted by the executive committee of the Public Relations Section of the preceding year, the section has undertaken a survey of public utility education in the colleges and universities. The object of this survey is to determine:

1. The extent to which there is a study of public utilities in college and university courses.
2. The character and extent of the industry's demand for college-trained personnel.
3. The character of the opportunities open to college-trained personnel in the industry.
4. The willingness and ability of the industry to co-operate with colleges and universities.

For this most important work the association secured a man eminently qualified by training and experience to conduct the survey, Professor C. O. Ruggles, dean of the College of Commerce and Administration of Ohio State University, who was granted a year's leave of absence to undertake this survey. The details of the survey will be presented to you by Dean Ruggles at one of the sessions of this convention. Let me say, however, that in my judgment this is one of the most important activities ever undertaken by this association, and in its conduct we have had the most hearty, whole-souled co-operation from the colleges and universities of this country.

The need of continuous public information as to the fundamentals of our industry is becoming increasingly apparent. There is no better medium for presenting this information to the public than the local newspaper, interested as it is in the local community and all that pertains to its advancement. With this thought in mind there was prepared under the direction of this section an advertising copy service which has furnished to the member companies suggested copy for publicity matter to be published in the local newspapers. That this service has been worth while is evidenced by the extent of its use and commendations of the character of the copy.

## Committee on Civic Development

THE prosperity of any community and of the electric light and power company serving it go hand in hand. There is a mutual dependence which this industry clearly recognizes. Community growth and development is dependent upon the ability of its utilities to keep abreast of community expansion, and, conversely, the growth of any utility is measured by the development of the community it serves. Realizing this mutual interest, there was organized a new committee, the civic development committee. Its purpose is to interest our member companies in co-operating with every interest working for community development. Of necessity the work this year has been largely that of organization and survey.

In co-operation with the Metropolitan Life Insurance Company a conference on the migration of industry was held which was largely attended by business executives from every section of the country. We believe the work of this committee will be one of major importance to the country and to the industry.

## *Insurance Committee*

PRIOR to the present administrative year the insurance committee had concerned itself largely with the question of rates for various classes of insurance carried by our member companies. This committee by presenting to insurance companies an accurate summary of insurance experiences has obtained substantial reductions in rates for fire and casualty insurance. The committee is to be commended for its efforts and accomplishments. In these accomplishments your insurance committee and the representatives of the insurance companies have worked harmoniously.

There are, however, other points of mutual interest. Both interests are concerned with the formulation of all rules and requirements pertaining to the installation of electric wiring and equipment. The insurance companies of this country are large investors in the securities of this industry, and there often arise questions involving matters of policy. In view of these mutual interests the scope of the insurance committee has been broadened and its personnel has been enlarged to include not only insurance technicians but executives who can meet with the executives of the insurance companies to discuss matters of policy whenever occasion requires. Arthur Williams, past-president of the association, has undertaken the important work of chairman of this committee.

## *Geographic Divisions*

YOUR president has attended the conventions of every geographic division, with the exception of the Canadian Division. It is a great pleasure to be able to report to you that the work undertaken a few years ago of organizing the geographic divisions is bearing fruit and that these divisions are now functioning effectively and rendering a valuable service to their member companies.

The several committees of these geographic divisions are, in so far as local conditions warrant, co-ordinating their work with that of the similar committees of the national association. These committees have a comprehensive grasp of the character of the work to be done and of the methods to be adopted in its accomplishment.

## *Rural Service Committee*

THE rural service committee has directed its activities toward assembling, digesting and publishing the results of the experiments which have been carried on for several years through the farm experimental lines established in various sections of the country. Out of the work of this committee has come a growing appreciation on the part of the farmer of the desire of our industry to co-operate with him in solving this very real problem of farm electrification and a better understanding of what is involved in the extension of electricity to the farm.

The work of this committee has developed slowly but surely. We have endeavored to make certain in what way electric service can be used with profit to the farmer and to avoid saddling upon the farmer electric equipment poorly adapted to his needs. This means time, but it will, I believe, prove to be time well spent.

In co-operation with the local utility, arrangements have been completed for the establishment in the State of Maryland of a permanent national exhibit of farm electrification. This exhibit will display every known adaptation of electricity to farm work and, being situated near the nation's capital, which is visited yearly by thousands of people from all sections of the country, will, we hope, prove a national attraction.

## *Exhibition Committee*

THE work of the exhibition committee speaks for itself. A visit to the splendid exhibit on the pier adjoining this auditorium is a most liberal education to all concerned in the electrical industry. No one can afford to leave this convention without a thorough inspection of this exhibit. The association wishes to express its appreciation of the splendid co-operation of this committee in carrying out the many difficult details connected with this exhibit.

## *Society for Electrical Development*

DURING the year the Society for Electrical Development has been completely reorganized, and it now constitutes an effective medium for carrying out the work which its name implies, electrical development. As now organized, the four major branches of the industry—the manufacturer, jobber, contractor-dealer and the electric light and power companies—all have equal representation on its board of directors. Under the auspices of the society an industry sales conference has been organized and is now engaged in the preparation of a plan for intensive development of residential business.

Your association has whole-heartedly co-operated in this reorganization. W. W. Freeman, president of the society, is to tell the convention of the society's work and plans.

## *Federal Trade Investigation*

ONE of the outstanding events of this year has been, and still is, the investigation being conducted by the Federal Trade Commission. Before it commenced spokesmen for the industry said over and over again that there was nothing to fear from an honest inquiry and that there could be no objection to it. That still remains our attitude. We want it to be most searching and complete. We are anxious that the true facts be given to the public, that the people of the country may see and understand the make-up and habits of the organizations that furnish them the light for their homes and the power for their factories.

The National Electric Light Association, the Joint Committee of National Utility Associations and every organization representing the utilities, whether national or local, have thrown open to the commission everything in their possession. Minute books, account books, receipts and expenditures, vouchers, correspondence—in fact, every scrap of paper—have been made available for scrutiny. Every publication issued, every address delivered, every news release made, has been made available for examination by commission representatives. More than 2,500 separate exhibits have already been introduced and made part of the record, and accumulation still goes on.

It is easy to get a false impression of the investigation and of the manner in which it is being conducted. As we read daily in certain newspapers distorted versions with startling headlines and see prominently displayed photographs of letters and checks, we get an idea of sensationalism and perhaps visualize the hearings as exciting scenes. In fact, they are nothing of the kind. They are conducted quietly and peaceably. The atmosphere is that of a court room and the proceedings consist largely of the routine identification and orderly introduction of documents. That is the way in which the record is being made upon which the commission will finally base its findings and recommendations. The record gives the true story of what happens and it can be found nowhere else. That story is quite different from the narratives with which we are daily regaled in some of the daily newspapers.

### The School-Book Situation

Let us consider, for instance, the school-book situation. Under the direction of the state committees of public utility information, pamphlets dealing with electric light and power, gas, telephones and street railways have been published and furnished for use in the public schools. From some of the newspaper accounts, one would think that the utilities, in some mysterious manner, have forced innocent school officials to compel their students to learn falsehoods from textbooks composed of propaganda, or else that there has been a conspiracy between utility companies and school teachers to pervert the youthful mind.

It is an insult to American intelligence to believe that the utility companies would ever undertake such a plan, or that the thousands of earnest, hard-working school teachers throughout the land would allow it to be carried out if attempted. The men and women who teach the youth of our country must resent this imputation on their intelligence and their integrity. The American people will not believe that they are either fools or scoundrels. I do not speak on their behalf, but as to the utilities, I say that if they had ever undertaken any scheme to corrupt instruction, the individuals who were guilty of it could not be too strongly condemned and would already find themselves beyond the pale of good utility society. Of course, the answer is that no such thing has ever happened, or could conceivably happen. The very record before the Federal Trade Commission shows that it did not.

It is true that the utilities have furnished material for the use of teachers in the schools. They have done so openly, frankly asserting authorship and gladly assuming responsibility. No teacher has ever received copies for such use unless, after reading a sample, he or his school superiors have decided that it was useful to him and his students and asked that it be furnished. For several years the utilities have been giving this assistance to teachers. It is a public service known to everybody with school connections. It has been welcomed and appreciated, as thousands of letters of thanks testify. It remains for a certain type of press to discover and declare an evil in it.

What is the material that has caused all this disturbance? Is it a discussion of the theories of government, of private against government or municipal operation, or of any other controversial subject? Not at all. It tells about inventions, and turbines, and transformers, and transmission lines and ohms and amperes and kilowatts and the other things that go to make modern electric service possible. If I were stirred to any emotion at all by such matter, I might sympathize with the school child who has to put in his time studying it; but I would not worry about the effect on his political or economic opinions.

The pamphlets are almost pure statements of undisputed facts. It was intended that they should be so. As stated by one of our able executives, in testifying before the commission on this subject, the school pamphlets "are as strictly informative as it is possible to make them with the intelligence that God gives." That was the purpose. That was the way they were written and the way they still appear as introduced by the commission itself in the record.

Perhaps the best proof of the excellent character of these pamphlets, of their unbiased presentation of the subjects, is the fact that adverse critics have been able to discover practically nothing with which to find fault. Out of the scores of pamphlets introduced in evidence, only one paragraph from one copy from one state, not found in any of the others, has been held up to public gaze as an improper statement.

It is important, as these hearings proceed from day to day, that we keep a proper sense of perspective. Let us not magnify a detail until it absorbs the foreground. It is the completed portrait that will count.

### Human Frailty Exists

Human frailty exists in our industry as in all others. In an investigation like this, involving every act during the life of thousands of companies, hundreds of thousands of separate transactions, sales and purchases of properties, and manifold issues of stocks and bonds—business arrangements carried on by a multitude of individuals for the last quarter century—it would be miraculous if there should not be found some instances of bad judgment, of the influence of greed, even perhaps of actual wrongdoing. Such instances, if any be found, will, I am certain, represent a very minute percentage of the transactions under investigation.

None of us has yet attained perfection, and, besides, a transaction scrutinized with the hindsight of today may have quite a different aspect from that which appears when viewed in the light of the facts and circumstances surrounding its origin. Each association, each company, each individual must take responsibility for its or his own acts, receiving the credit or the blame that the record brings. Every tub must stand on its own bottom. Blame, if cause be found for any, should be placed where it belongs. The entire industry should not be condemned because of the misdeeds of a few, if any. The public utilities today are in the vanguard of American business. They are proud of accomplishments of the past; they do not fear the proceedings of the present; they are confidently carrying on their plans for the future.

Of late there has been some public criticism of the activities of the association. Such criticism discloses a gross lack of understanding of the character of the activities criticised. In the past few weeks certain portions of the public press have carried statements to the effect that the annual budget of the association, amounting to approximately $1,444,000, has been expended wholly for the purposes of propaganda and that this expenditure constitutes a burden on the consumer of electric service which he should not be asked to bear. There is nothing in the record or in the facts to bear out this statement. Such a statement completely ignores the many other activities of the association, all of which are maintained in the interest of good public service and, because of the co-operative character of your association, are carried on at a most reasonable cost to the industry.

The total annual cost of carrying on all of the activities of the association, including the refunds to the geographic divisions, amounts to approximately sixteen one-thousandths of a mill per kilowatt-hour sold to the public, or between four and five cents per customer per year. The amount which the association expends annually for the work of public information, which has been termed "propaganda," does not exceed $50,000—less than one-third the amount we are expending alone in the furthering of the extension of electric service to the farms of this country. The so-called "burden" laid upon the consumer annually can be reckoned only in fractions of a cent.

In particular, criticism has been directed to our work with educational institutions. In some instances it has been charged, referring to our co-operation with colleges and universities, that we are endeavoring to subsidize these institutions and use them as mouthpieces for the industry. Nothing could be further from the truth than this charge. We have been co-operating with educational institutions. We are now co-operating with them, and I hope shall continue to do so so long as these institutions desire our co-operation.

The purpose of this co-operation is to ascertain the material needed by these institutions to enable them to conduct their courses in public utilities on the bases of fact as applied to present-day practice and, once we have ascertained the material needed, to render such assistance as we may be able in placing such material in their hands, to be used, however, at their discretion. In no instance has the association endeavored in the slightest degree to coerce, to subsidize or to direct in any way the conduct of these institutions.

The time has long since passed when the purpose of a collegiate education was to fit men and women for the so-called professional careers alone. Today business is regarded as one of the greatest and most important of the professions, and out of the conduct of business as constituted today has come a new profession, the profession of management. It is of the utmost importance to every interest in this nation that our young men and women leaving our colleges to enter the field of public utility business shall be thoroughly grounded in the economics of that business.

No industry has a greater concern than ours in the integrity of our educational institutions. The charge is laid at our door that we are "propagandists," the purpose of this charge being evidently to discredit the work of public information. In so far as a propagandist is one who disseminates information based on fact, we plead guilty with pride. No matter how severe or how bitter the criticism, we must not relax our efforts to acquaint the public with every phase of our industry. We cannot do otherwise if we are to keep faith with the public and adequately discharge our service obligation.

I have an abiding faith in the integrity and the ability of the American public to deal fairly with our industry once it is possessed of the requisite information for the exercise of intelligent action and the formulation of sound judgment. If we, because of adverse criticism, indifference, or for any reason whatsoever, fail to see to it that the public has such information, then we must not blame the public if at times it fails to accord to us that measure of justice to which we feel we are entitled.

This industry is justly proud of its record. The high standard of living which has been attained in this country, higher than that enjoyed in any other country, would have been impossible without electric service. The men and women engaged in the industry are deeply conscious of their duty as public servants and are earnestly and conscientiously striving to discharge that duty. They are proud of its accomplishments, but their pride is measured not in dollars gained but in service rendered.

## *Suggested* MERCHANDISING STANDARDS*

*1. The general sale of electric devices at margins commensurate with the cost of selling is the only sound merchandise practice and is conducive to constructive building in the appliance merchandising field.*

*2. When combination sales are advisable, adequate margins should govern selling prices. Only the "true value" of articles should be stated in the advertising.*

*3. Deferred payments in connection with the sale of all merchandise are universal practice and are accepted by sound financial authority and favored by the public. A period not exceeding eighteen months is recommended as a maximum time allowance for load-building devices in the pioneering stage, and a period not exceeding fifteen months for financing motor-driven devices having general public acceptance. Relatively shorter terms, on a self-supporting basis, should be extended on items selling for less than $25. A carrying charge for financing service should be made in all cases and an initial payment be required large enough to constitute a sale.*

*4. The power company is in the merchandising business for the promotion of devices which constitute a medium of electric service. There are kindred lines of merchandise which are naturally used in conjunction with the appliance, but we suggest that it is not desirable for the merchandising department of the power company to engage generally in the direct sale of non-electric devices.*

*5. We recommend an adequate classification of merchandising accounts by the National Electric Light Association.*

*From report of general merchandise committee.

# Industry Public Policy*

### Rate reductions outstanding achievement. Economic trends and public reactions. Government and the utility business

By R. H. Ballard
*Chairman Public Policy Committee*

*R. H. Ballard*

ONE year ago in this city the National Electric Light Association held its fiftieth convention. As is customary when we pass one of the major milestones, our thoughts turned back to the early days of this industry which has contributed so much to our country's prosperity—to the earnest men who, in the face of every conceivable discouragement, persisted in their studies of the newly discovered force; to the progress of the new art, halting at first but gradually gaining momentum until every corner of the civilized world now pulsates with this invisible energy.

On such occasions we are prone to feel that our work has been good. It is not easily apparent where further progress can be made, yet in the year that has passed since the last meeting great things have been accomplished. In many respects it has been one of the most notable years in our history. In financial matters the stability of the industry has been evident in the widespread market for its securities to the point where they are held in ownership by millions of people. Technical progress of a remarkable character is shown in the constantly increasing efficiencies of our generating plants and transmission and distribution systems.

## Rate Reduction Outstanding

By intensive work in our commercial departments electrical appliances have been introduced into homes and factories in greater number than ever before. Not only does this mean greater comfort and convenience to the housewife and the artisan, but this larger market for our product, coupled with the increased efficiencies effected, has enabled us to make substantial reductions in our rates. In fact, rate reduction with continuous improvement of service is probably the outstanding achievement of the past year.

In the face of these constructive accomplishments, of which the buying public is the greatest beneficiary, the electrical industry has been subjected to a campaign of unfair publicity. Any investigation of the electrical industry which considers more than minor details will disclose that it has been developing along natural economic lines; that when unjustly attacked it has defended itself and has sought a fair hearing at the court of public opinion. The phraseology used by its critics is different, but when their remarks are carefully analyzed these are the things of which they complain: Ignoring the possibility that the same economic conditions which have brought about the chain store, the chain bank and the chain newspaper might also account for the chain utility, they have directed criticism against concentrated ownership and management, but only as applied to public utilities.

In the April issue of the *North American Review* there was a splendid article, entitled "Newspaper Mass Production," written by Roy W. Howard, the directing genius of a nation-wide chain of newspapers. In this article he argues that group production of newspapers is a sound practice in accord with present economic tendencies, by virtue of which the ultimate consumer is distinctly benefited. As the following quotations from Mr. Howard's article are read, it is suggested that the expression "public utility" or "electric power" be substituted for the words "newspaper" or "journalism" as they appear:

"The task of producing daily newspapers successfully is today a most complex operation, involving the superimposing of professional efforts upon a solid business foundation."

"Mere magnitude in an enterprise suffices to terrify a certain type of mind."

"'Chain journalism,' as its critics prefer to designate it, is nothing more than the editing and operation of a group of newspapers in different cities by a single corporation or a group of corporations, with a centralized control."

"Chain newspaper operation needs no apology. Newspapers in the long run, almost without exception, succeed or fail according to their ability to serve the public interests of their community. What is true of a single newspaper is equally true of a group. That chain operation makes for financial stability even critics of the system will admit."

"A frequent objection to chain ownership is that it results in standardization. After all, the answer to this indictment is to be found in whether the standardization produces a better product for a larger number of people."

---

**Address before the N.E.L.A. convention, Atlantic City, June 4-8, 1928.*

"Production of a daily newspaper of today has become a complex job—the work of highly skilled experts. Chain operation enables the mobilization of this high-priced talent at a minimum cost to each unit of the chain."

"The public has no desire to see this country governed by its newspapers any more than it desires to see it governed by partisan political bosses."

Your public policy committee submits that Mr. Howard's article is a clean-cut statement explaining why no American enterprise, newspaper or public utility, if it is to meet its obligations of adequate service to the public, can afford to ignore the natural economic trend.

That the electrical industry has taken steps to defend itself against the unwarranted attacks of a group whose every act indicates a lack of practical knowledge in business affairs is but natural. Theorists of this type have advanced unsound ideas from the day of our independence. They would remove from the electrical industry all of those men who have established its present sound position and in their stead substitute men whose guiding thought is political rather than economic.

### GOVERNMENT IN BUSINESS

When the leaders of the electrical industry, serving 95 per cent of the country's electrical output under private enterprise, take legitimate steps to inform the public of the unsoundness of these proposals, the cry of "meddling" is raised. Government in business professing opposition to the general application of government operation of the entire electrical industry, there are some who advocate that certain large projects should be governmentally operated. Under the false argument of establishing tests of performance, they would substitute government competition for regulation; they would compromise with vital principles underlying the nation's progress and would substitute the views of a small group in public or private life for those of the vast majority of the people who believe in private initiative and enterprise. Those responsible in public life for the local regulation of utilities are satisfied that the states are competent to regulate their own utilities and that there is no general demand for the federal government to enter this field.

In the far West it is proposed to build a gigantic power dam for the avowed purposes of flood control, reclamation and domestic water supply, although, in fact, these latter services would be jeopardized and delayed by their inclusion in an uneconomic power development program. In the South it is proposed to enlarge a scheme of government ownership and operation, in the hope that the greater enterprise may prove successful, although the lesser project has so far been an economic failure. In these regions are men who have spent decades in the study of local power needs and have carried out engineering enterprises to meet these needs. By the very nature of things these are the men who are best informed to advise the public regarding further power development, but when these experienced men attempt to speak they are met by criticism, coming from advisers of the people of the same type that heckled the founders of the Republic.

With the obligation of public service goes the responsibility of using due diligence in the development and the protection of our business and to conduct its operations fairly and efficiently. This we have endeavored to do.

Every business has certain facts with reference to it known best to those actually engaged in it. Time and experience have established these facts almost like the laws of the Medes and Persians. Those not experienced in a business are as likely as not to obtain somewhat distorted ideas concerning it. Indeed, it is not unusual to find people presuming to know more about the electric light and power business, for example, than the men who have spent their lives in it. It would seem, therefore, that this industry is not only well within its rights in presenting facts concerning itself to editors, educators, and to the public, but that it is in duty bound to do so.

The schools of the country are shaping the thought of the oncoming generation with reference to all business, economic and social matters, and it is important that they should have the facts. The electric development of this past decade has brought great economic and social changes, and your industry has been active in making available to the properly constituted authorities of the schools the facts concerning its development. What better source have the schools for obtaining information on the electric light and power industry than from those engaged in its development? Do men consult a lawyer when they are sick or a physician when they are in need of legal advice?

---

## *Principles for* MERCHANDISING*

*1. All discussions of the problems of the relations of light and power companies and dealers selling electrical appliances must be based upon proper and adequate service to the ultimate consumer.*

*2. There should be a segregation of the accounting of the merchandising departments of power companies from their public utility functions, and all items of expense incurred in the merchandising of appliances should be charged to the merchandising activities of the companies concerned.*

*3. It is recognized, however, that expenses incurred in the pioneering of appliances which have not yet met with sufficient public acceptance to be merchandise items in the stocks of local progressive dealers, and general advertising for the development of the market for appliance service, should properly be charged to the promotion accounts of the utilities and not charged to merchandising.*

*4. This conference recommends to power companies and independent dealers the necessity of constructive co-operation in their local fields for the better development of the electrical appliance business.*

---

*From report of general merchandise committee.

# Statements to thi

## *from the N.E.L.A. Convention*

I HAVE an abiding faith in the integrity and the ability of the American public to deal fairly with our industry once it is possessed of the requisite information for the exercise of intelligent action and the formulation of sound judgment.

[*H. T. Sands*]

◆

THERE is a force within this country mightier than your multiplied motors, dams or power stations, and that is the united heartbeat of the American people, and much as the orator would sweep his audience or the evangel move the erring, get your spiritual batteries charged and play upon the ideals and emotions of our people.

[*Clayton Rand*]

◆

I FIRMLY believe that the electric industry will continue to be characterized by policies of fairness, open publicity and frankness, co-operation with public authorities, and above all by scrupulously living up to all the implications of its position as a public service industry, perfecting its machinery for self-regulation and control from within.

[*Melvin A. Traylor*]

◆

NO AMERICAN enterprise, newspaper, or public utility, if it is to meet its obligation of adequate service to the public, can afford to ignore the natural economic trend.

[*R. H. Ballard*]

◆

THE first plank in the platform of good public relations is good service.

[*E. C. Stone*]

IN 1927 a total of 246 utility companies in the United States sold directly to consumers 3,581,206 shares of stock having a par value of $263,527,269. The 1,681,768 customer-ownership stockholders have invested $1,600,000,000 in utility securities.

[*Philip G. Gossler*]

◆

WE ARE just entering an epoch of development of the industry which demands the sale of more energy, and the company whose executive backs up his sales manager, not only with money, but with intelligent teamwork, will reap the harvest of more energy sales in full measure.

[*E. W. Lloyd*]

◆

ALMOST daily we have brought to our attention examples of what wonders interconnection is doing in the way of improvement of service, and almost daily we are missing opportunities to tell our customers—to tell the people of the communities in which we operate—to tell the nation what we are accomplishing by interconnection, of what interconnection is doing, of the fundamental thing that we are striving for in interconnecting.

[*George N. Tidd*]

◆

WE BELIEVE that the cause of public service in its broadest aspect can be best served and the development of the industry promoted by giving full play to inventive ingenuity, to constructive financing and to sane and logical extension of the service we give. We believe these activities would be stifled under political ownership and management.

[*Franklin T. Griffith*]

# nk About

LET us take as our common objective the promotion of knowledge and integrity in the art of industry and in the upbuilding of manufacture and trade.

[*Deane W. Malott*]

⁂

THERE is no way to cope successfully with organized error except with organized truth. Only a renascence of patriotic interest in government on the part of the better-informed and more responsible elements of society can accomplish needed reforms.

[*John E. Edgerton*]

⁂

IF YOU are desirous of hastening the utilization of electricity in the solution of railroad problems, there is scarcely any service you can render of greater importance than that which looks toward the development and standardization of the art of producing electrical energy and its application to steam-railroad operation.

[*L. A. Downs*]

⁂

ELECTRIC utilities are essential to public wellbeing and are necessary to national welfare and national progress. The regulatory bodies and the public at large must not only seek protection against exploitation or oppression on the part of public service corporations, but must also seek for that attitude which will continue to foster private initiative and efficiency, to stimulate improved methods and increased effectiveness, to preserve superior facilities for the business man and the worker, to improve the standard of living for the American home. These ends will be attained not by litigation, not by regulation, but by intelligent and wholehearted co-operation of all concerned.

[*Henry G. Wells*]

I COME to the conclusion that your system of selling is incompatible with the best merchandising practice. It may be effective for the small store in the small town. But it conflicts fundamentally with the necessities of large-scale, economical and efficient merchandising practice, and a more effective way out must be found.

[*Oswald W. Knauth*]

⁂

THE farmer of today is machinery-minded and is thoroughly sold on the value of electricity. The farms of America offer to the public service companies a great undeveloped field for expansion, a field that is ready and impatiently waiting for that expansion.

[*Clifford V. Gregory*]

⁂

OF THE seventeen million wired homes in the United States, at least ten million are so incompletely wired as to preclude the possibility of extensive use of electricity in removing the drudgery from household tasks.

[*M. C. Huse*]

⁂

THE function of the investment or holding company is getting more and more to be that of adviser, and the authority to manage and operate is being more and more localized in the local officers of the company.

[*A. W. Thompson*]

⁂

SEVENTY-FIVE per cent of American industry is electrified. Power has wrought an increase in the value of products per wage earner from $1,000 in 1850 to $7,500 today.

[*H. W. Derry*]

⁂

THE purpose of a price policy in any industry is to develop the maximum of business at a minimum of cost, a result of mutual interest to producer, merchant and customer.

[*Edwin Gruhl*]

# Golden Rule Relations*

The job of informing the public is the job of each utility man. New conceptions of service introduced. Executive interest necessary

By J. F. Owens
*Chairman Public Relations National Section*

PROPERLY to inform the public we are privileged to serve is a function of our industry second only in importance to adequately, economically and efficiently serving that public. Both functions are vital to the well-being of our industry and our duty to the public.

Upon these fundamentals the committees of the Public Relations National Section based their program and their endeavors to vitalize the program during the year.

### Complete Job Needed

Two major activities were undertaken as broad phases of the program which resulted from the organization meeting.

1. Encouragement, through committees peculiarly adapted and organized, of action on the part of member companies that would make for greater efficiency on the part of company employees, with particular emphasis on the necessity of executives informing and training those employees whose duties bring them in immediate contact with the public.

2. A clear visualization of our service relations to the public. Through the committees that were formed for the purpose of bringing member companies to a realization of these relations, the second phase of the section's functions was planned. Even though mechanical equipment may be the latest and best and thoroughly suited to the task of giving a full measure of service; even though the personnel may be loyal and industrious, yet this is only half the story. There is another party to the question of service. That party is the public. It matters little that the mechanical and human equipment of the organization be all that any one could desire; that the service be above criticism, if the second party to the service contract is not fully informed, thoroughly cognizant of what it is getting in the way of service, and satisfied that the service is being furnished at the lowest possible rates. Therefore, the public must be informed.

*J. F. Owens*

Perhaps the major activities during the past year have been directed toward awakening member companies to a keener realization that their job is only half done when service is made available at the meter, accounted for and payment made, but that quite as much their duty as the rendition of service, is the complete dissemination of such information as may enable the recipient of service to use that service wisely and well, and over and above all such information, presentation of such facts about the service as will prevent him from becoming an easy prey of demagogues with only self-interest to serve. The customer must know that his service can approximate perfection only when he, the second party to the service, responds with that full measure of co-operation, born of a knowledge that he not only is being adequately served, but that he is being honestly served.

On this premise the executive committee of the section early in the year requested headquarters staff, under the direction of George F. Oxley, director of public information, to prepare for submission to the committee a series of advertisements that might either be used by member companies or serve as suggestions in the preparation of copy for their own advertisements. Advertisements were prepared, approved by the executive committee, and a weekly newspaper advertising copy service inaugurated. These advertisements are being widely used throughout the United States.

The effect of this movement has been twofold: First, the advertisements themselves carried a terse, definite message to the reading public—a message drawn from men and women of our country whose opportunities to study and evaluate the electric light and power industry of this country have been notable. It brought to the people of the country observations of men and women, who, through their achievements, have reached places which warrant their statements being accepted at par. Second, as valuable as the effect of the advertisements themselves, is the attendant effect on member companies, hitherto not consistent advertisers: a realization effected that they have only been partially discharging their obligations to the public when they content themselves with merely rendering service, without providing with it a full and complete fund of information to insure proper use of that service by customers. Thus, the advertisements performed a dual mission.

---

*Address before the N.E.L.A. convention, Atlantic City, June 4-8, 1928.

### More "White Space"

The committee believes that the press is the best medium for disseminating information. It believes that it is the duty of every utility company to utilize the press, through paid advertising columns, to give to the public a straightforward, well thought out and carefully prepared account of its stewardship. But it is recognized that we cannot overlook other media of information—the spoken word, the daily contact of employees with their neighbors and friends. All possible factors should be utilized in giving true information about our business.

> *The job is only half done when service is made available at the meter, accounted for and payment made.*
>
> *Every utility company should utilize the press, through paid advertising columns, to give to the public a straightforward, well thought out and carefully prepared account of its stewardship.*
>
> *The commercial man, as he goes forth to interest a prospective customer, visualizes himself as a bearer of good tidings.*

There can be no doubt but that in the past there has been a contest, if you please, between the demand, on one hand, by customers for service, and, on the other, the necessity for securing capital and equipment to provide that service. The time and attention of those responsible for the company's performance have necessarily been devoted to what might be termed the material side of rendering service. While executives and their co-workers have been busy selling to financiers the opportunities that lay ahead of them; while new demands for service have created conditions that required new equipment, naturally the genius of the industry has been turned toward its material development. Men have been busy thinking out ways to do new and better things than they ever did before. Superintendents devoted their time and effort to reducing manufacturing costs, cutting down transmission losses and effecting operating economies. Inventors were developing new equipment and new appliances for greater utilization of service.

In short, the best brains of the industry have, of necessity, been chiefly concerned with the material phases of the business. Service demands increased day by day and the industry grew by leaps and bounds. Exigencies of the hour demanded greater efficiency in generation and larger units of production and operation. These conditions called for consolidation. Small, inefficient companies must unite in order that the economies that come only through employment of large manufacturing units could be secured.

Executives were busy doing the job. Their energies were directed toward this internal development. While this was going on, there were others who, prompted by purely honest motives, were beginning to fear the size to which the industry was growing. And there were others with less worthy motives, who saw an opportunity to capitalize this fear and who, by the utterance of untruths, half-truths, or distorted statements, wilfully and sometimes maliciously encouraged the somewhat latent fears of many right-thinking men.

It was then that leaders of the industry awakened to the realization that they had left at least half of their job to those who, either through lack of understanding or unholy motives, were making a miserable botch of it.

Far-seeing men determined that organized effort must be made in an attempt to bring every member company to a realization of the truth; that in addition to the rendition of service at the lowest possible rate commensurate with good service, their trusteeship to the public demanded that the service carry with it the information which they alone were in a position to provide and that a vital element in stability of service and service companies was public co-operation.

In former years the engineer was content if his turbine measured up to standard and met all of the known tests for satisfactory performance; if his transmission lines met the requirements of recognized engineering standards and practices; if his substations were adequately and properly built and if his meters were accurate. The accountant was content if his records presented a true picture of the company's operations; if he could supply the executives information necessary for a study of the company's operations and a forecast of future requirements, and if bills for service were accurate and complete. The commercial man felt that his job was adequately performed when he secured a contract for service.

Today, the engineer sees not only his turbine as machines; his transmission lines as so many poles, wires, insulators and anchors; his meters as accurate measuring devices. His vision extends through and beyond these material elements to the ultimate customer. He pictures himself as the instrument, through whose genius a service is brought to a waiting public, a service that shall shorten hours of labor and provide moments of leisure that may be employed in a development of the finer things of life, the training of mind, and permit a reaching out for cultural advantages that make for complete manhood and womanhood. The accountant knows that his records are more than mere figures upon reams of paper. He realizes that service bills transmitted to customers offer an opportunity to carry a distinct message, a readable message to be easily understood and analyzed by one who does not understand the technicalities of modern bookkeeping. The commercial man, as he goes forth to interest a prospective customer, visualizes himself as a bearer of good tidings. He senses that securing the contract is only half the job; that it is his duty to give the customer a friendly understanding of the company he represents; that the customer be made to know that the company's mission is not fulfilled when a plant is physically connected to his lines. He realizes that his job as a company representative is only begun when he secures the customer's business, and that his major obligation is to keep in constant touch with the customer, to be his friend, his confidant, his adviser

and to be on such a footing of mutual understanding that the customer will call on him instinctively for counsel and advice in the utilization of his service.

But men come and go, engineers change and give their places to others. Customers change too. If it is true that our job is only half done when, as utility men, we inspire the members of our organizations to realize the largeness and the opportunities of our business and that they are really emissaries of a new order; if it is true that half our job is to fully inform our customers concerning our companies, our policies and our aims, then this task of creating and maintaining proper relationships with our public is never ending. More and more will it require the best thought and brains of the industry to bring about and safeguard a mutual understanding. More and more are we not only justified, but definitely obligated, to employ every legitimate means to properly inform and impress the public. More and more will it be necessary to employ the best methods for the dissemination of ideas, to provide the facilities of a clearing house for information and practice and to encourage the laggards, if there be such. The claim upon our industry of this obligation is quite as definite, if not as insistent, as the obligation of service.

The Public Relations National Section functions, in its present set-up, through eight separate committees. Each of these is submitting a report of its activities during the past year and each has pursued a course of action, predicated upon the major functions of the section, as outlined in this report. Some of them, particularly the women's committee, include both major functions. The work done by these committees merits a comprehensive and detailed report. But the men who have been responsible for this work are best fitted to tell the real story of their operations and their reports are being presented at this convention.

## Investment Diversification Good

By Dean John T. Madden
*New York University*

THE tendency that will show itself more and more clearly is that of lessened investment in individual companies and a broader diversification in the investments in order to distribute the risk. The investor in securities of an electric light and power investment or holding company has at once diversification and distribution of risk, and if the investor happens to be a manufacturing corporation, it, too, has additional diversification and distribution of risk.

If the trend toward one of the several forms of amalgamation is to continue—and it probably will—the investment company may be one of the devices by which the number of loss-producing companies will be reduced. I can unhesitatingly say that history will reveal public utility financing to have been more free from taint than that of any other industry taken as a whole.

# Utilities and the Public*

### Electrical industry faces a critical situation. Its future depends on its own actions. Regulation and rate of return

By Henry G. Wells
*President National Association of Railroad and Utilities Commissioners*

*Henry G. Wells*

TODAY the electrical industry is prosperous. Its growth has been rapid. The possibilities for the future are tremendous. But already there are signs of unrest, and the responsibility is upon you to determine by your acts whether the industry shall continue on its course normally and properly—whether the great mass of the public shall continue to have confidence in those in charge, or whether those who are at the moment attempting to discover evils to present to the public are to receive encouragement from some in your midst who may adopt unwise policies and unfair methods. The public will not be governed by what you say but by what you do. They look not for promises but for results. If an investigation develops any substantial number of facts that the public does not like, it will not only be those involved who will suffer but the whole industry.

If a small minority of your membership fails to live up to the principles of this organization, the organization suffers. Strenuous moral suasion may be necessary on the part of the majority to protect itself from the results of unwise action of that minority. The great mass of the public today do not sense any great evils; they are not convinced that there is anything substantially wrong. But it may not take much to change the picture. And so it behooves those directing and guiding this great industry to walk circumspectly. They must be fair. They must be not too selfish.

Because an industry is big and because it has had a tremendous development it furnishes an opportunity for attack. But the American people today as a whole do not get enthusiastic over attacking anything merely because it is big. Henry Ford has built up one of the largest industries in recent years, yet has been comparatively free from hostile criticism by the public—at least while he confined his activities to his business. And so, while the size of your business furnishes an ample target for the few, your conduct can be such that the acquisition of recruits to shoot at it will be difficult.

## Factors of Responsibility

There are two factors in the case of the electric industry which make it even more imperative to realize the great responsibility involved: First, the electric company is usually a public service corporation; second, as such it is granted privileges by the state and municipality and even in most cases allowed a monopoly in its business.

Many arguments are presented from time to time to justify certain acts of the utilities because in many respects the utilities have factors of ordinary business, but often it is evident that the utility officials overemphasize those factors and do not sufficiently recognize the distinction that exists and which should control in their public and business relations. The utility industry is protected in many ways because it is a public service corporation. It enjoys many advantages that private industry does not enjoy, but it must expect to assume the duties that go with such privileges. There are some rights, however, that are common to all industry and all individuals.

The electric utility, like any other industry, has a right to be heard. It has the same right to present its views on matters affecting it as any other business. The electric utility, like any other industry, has a right to have its spokesmen at gatherings of the public. It has the same right to publish its articles in newspapers and magazines as has any other interest. The electric utility has the same right as anyone else to see to it that the education of the young shall contemplate both sides of any question.

The electric utility, like any other individual or organization, has a right to be represented at Washington and the various state capitals by its own officials or by paid attorneys—call them lobbyists or what not—so long as they conduct themselves properly. It has the same right to protect itself from unjust attack as is granted to others. It has the same right to correct false and misleading statements as anyone else.

It is an interesting situation when some of the stanchest advocates of free speech are attempting, by means of investigation, to give out the idea that a great and useful

---

**Abstract of address before the N.E.L.A. convention, Atlantic City, June 4-8, 1928.*

industry has no right to protect itself by means of free speech. It is an interesting situation when advocates of municipal or governmental ownership can set forth their arguments orally, by written articles in newspapers and magazines, and can even be found in the schools and colleges teaching the youth of the land the advantages of such a doctrine, yet they would deny you the same privilege. In one case it is educational, in the other it is propaganda.

Any fair-minded citizen will grant your organization the same right to present arguments for private ownership. Any red-blooded American will grant you the right of self-preservation by means of speeches, magazine or newspaper articles and proper instruction to the youth of the land. But there are certain obligations attendant upon these rights. The public have a right to expect fairness, no misrepresentations, no distortion of facts, no concealment, no evasions. It must be the spreading of truth and not misleading propaganda. They have a right to expect ethical conduct on the part of paid attorneys or agents.

### Holding Company Function

One or two weaknesses at this critical time may well be pointed out with a view to preventing the increase of recruits seeking pot shots at the large-sized target of the electric utility. One of them is the holding company. The value of holding companies, properly administered, is well recognized, in the co-ordination of common interests, the unification of a common purpose, the strengthening of the weak by the strong, the stability given to new financing and expansion and the possibility of better and more adequate service. But that strength is a source of weakness when directed to selfish purposes. When any company becomes primarily a stock-jobbing concern, when its aims are directed solely to the benefit of the speculators in such securities and not to the benefit of the subsidiary companies and the public they serve, then the public has a right to complain. When any such holding company issues securities far in excess of the worth of the underlying companies, it is a source of danger to the public. When any such company attempts to conceal excessive profits on the part of some or any of the subsidiary companies, such a policy is naturally the object of criticism and attack on the part of the general public.

Another potential breeder of target-shooting recruits has developed recently in my own state. And it isn't localized either. The same attitude is apparent in spots throughout the country, and the majority of regulatory boards are watching the situation with increasing interest. It is the attempt to set up reproduction cost as the sole factor in a rate-base valuation, coupled with the payment by large interests of exorbitant prices for the stock of well-managed and prosperous companies, relying on that type of valuation to secure a return on those high prices. It is only necessary to quote from one of your trade magazines to indicate where this may lead. Referring to a recent case, this magazine says:

"In one sense, it is to be regretted that the situation in this particular case did not require the court to find definite values for the physical property for actual (not theoretical) depreciation and for going value, and that it did not state what actually constituted a fair rate of return."

That should not be the attitude of the utilities, to advocate making the United States Supreme Court a fact-finding body. How far we have traveled since the early decisions under the Fourteenth Amendment. How much farther do you expect to travel? To my mind, the situation warrants a word of warning.

### Reproduction Cost

Reproduction cost assumes the reproduction of a plant which would never be reproduced exactly as is. It apparently assumes valuing a plant on a basis which would not always be considered in determining its value for some purpose other than for rate making. It often involves long and expensive investigations, complying with elusive requirements, and recognizing cumbersome theoretical opinions of experts, resulting finally in a composite guess. And when this composite guess is finally determined, the factors on which it is based may have changed so that it can no longer represent the true value and the whole process may have to be repeated. In fact, it would be quite possible to have a company before the regulatory commission and the courts almost continuously. "It does not enable justice to be done speedily and efficiently either to the public or to the investor. In periods of enhancement of prices the public may be compelled to pay excessive rates. In periods of depressed prices the investor is compelled to receive less than a fair return upon the capital invested." At times when companies might need speedy relief in the shape of increased income such relief might be unduly delayed. One wonders what the attitude of some companies will be if there comes in the course of the next ten years a marked decline in prices below present levels, particularly those companies a substantial portion of whose plants was built shortly after the war during the era of very high prices.

Of course, you will ask, what then will be the attitude of regulatory boards? Will they insist then upon reproduction cost as a base, as the public did in the first instance? And, no doubt you will quote Smythe vs. Ames, wherein the public's representatives were arguing for just such a basis as the companies are today claiming. Frankly, that ought not to be the position of the public or the regulatory boards. We hear a great deal about the prudent-investment theory of Massachusetts, but some of us are not committed to that as a proper theory to be binding upon us. Neither do we believe that with changed conditions the public would force us to adopt the reproduction-cost theory as the proper one unless we are forced to adopt it at the present time. We have had regulation for many years in Massachusetts and have not insisted on any hard-and-fast rule. We have sought and are now seeking simplification, and we believe that ought to be the aim throughout the country. Somehow it has seemed as though the coining of the word "valuation" was a mistake. "A fair return upon the fair value of the property" was a glib phrase which served its purpose at a time when conditions as to regulation and capitalization were more or less chaotic. But is it necessary today? Rather, is it not an unfortunate phrase when applied to present-day conditions? After all, is not the whole proposition an economic problem, pure and simple.

### Rate of Return

If rates are allowed or fixed sufficient to pay all proper operating expenses and maintenance charges—to pay taxes and interest on indebtedness, to set aside an adequate depreciation reserve and have a reasonable surplus left over after the payment of such dividends as will keep the market price of stock issued under the authority of the commission for proper capitalizable purposes at such a figure that new issues may readily be marketed having in mind the purchasing power of the dollar and its fluctuations—can any one say there has been confiscation in fact, whatever theoretical experts may argue? And those facts are not hard to determine. Operating expenses and maintenance charges are available from year to year from the annual returns, and the necessary evidence to show any present changes in them would not take long. The same is true as to interest and taxes. There would seldom be more than a slight difference of opinion as to depreciation, and any regulatory board must recognize the importance of allowing an ample amount for that purpose. Market value of the stock-purchasing power of the dollar, amount of dividends and of surplus are all matters of judgment, fairly easy of determination in the light of existing conditions at the time.

If economic conditions change, only a few weeks at the most would be required to change the rates. Some may say, "But that means prudent investment as a base." Not necessarily. Granted that indirectly most cases would work out that way—and probably therein rests the widespread opinion as to the so-called Massachusetts rule—yet one can readily imagine conditions arising where rates would be allowed more than necessary to pay a fair return upon the prudent investment but which, nevertheless, were deemed necessary from an economic standpoint.

Sounds simple, doesn't it? Regulation in Massachusetts *was* simple up to a year or so ago, and none of the companies complained that we were taking their property away from them. But now, instead of the few weeks formerly required for a rate case, what do we have? We have had some cases in which five or six months is required to present evidence to us, and probably two or three or more years will elapse before the court tells us whether our decision was right or wrong. And at the end of that period of time undoubtedly conditions will be such as to warrant starting the farce all over again. It will be unfortunate for the public and for the companies if that tendency becomes general. When extremely prosperous companies adopt this attitude, the public can only see a pretext to deprive them of what they are morally entitled to, a fair share in the prosperity, whatever may the legal principles involved.

Some of you are doubtless beginning to think I am unduly petulant over this matter. Rather am I apprehensive. It is brought to the attention of this great organization as a "stop, look and listen" signal. You ought to know wherein danger to your future can be minimized. You are facing a critical period in the history of the industry. There are those seeking to hamper you, and undue selfishness merely helps them in their aim. If what I have said seems unduly critical, it is said with the best of intent, to preserve this great industry for the benefit of the public and itself.

Electric utilities are essential to public wellbeing and are necessary to national welfare and national progress. The regulatory bodies and the public at large must not only seek protection against exploitation or oppression on the part of public service corporations, but must also seek for that attitude which will continue to foster private initiative and efficiency, to stimulate improved methods and increased effectiveness, to preserve superior facilities now provided for the American business man and the American worker, to improve the standard of living for the American home. These ends will be attained, not by litigation, not by regulation, but by intelligent and wholehearted co-operation of all concerned.

# *Reducing* Insurance Costs*

By Charles B. Scott

*President Bureau of Safety, Chicago*

*Charles B. Scott*

THE growth of the electrical industry and the present large units of organization have brought exceptional opportunities and responsibilities to every one in the organization to co-operate with the management in eliminating needless waste and effecting possible economies. The accountant has exceptional advantage in being able to assist in such an important undertaking because of constant evidence before him of these items of expenditure and their effect upon earnings. His opportunities also come from his relationship with the treasury department in maintaining the proper financial structure.

The insured usually interprets his insurance as a betting arrangement by which he may escape the payment of his losses because of his more advantageous end of the wager and the attractive odds offered. It should be needless for me to assure this audience that such an idea of insurance protection is entirely wrong. The fundamental laws of compensation apply to insurance, and eventually the insured must pay the penalty of his negligence and misfortune. The insurance company really finances these penalties over a period of time and thus makes the burden less noticeable. When the final accounting is made the insured and his associates receiving protection must not only pay the losses involved, but

---

**Abstract of address before the N.E.L.A. convention, Atlantic City, June 4-8, 1928.*

in addition to these the cost of administering the insurance business plus a reasonable return to the insurance company's stockholders.

For some reason, difficult to explain, the average business organization and individual carrying insurance handle insurance matters rather indifferently. Purchases of materials and supplies are made in a businesslike way The purchaser knows what he is buying and the fairness of the price paid. Insurance is too often purchased without any definite knowledge of what is being bought and with only a vague assurance as to the meaning of the policy granting the protection or the reasonableness of the cost.

This situation is in part due to the idea that coverage and rate making are highly technical and that rates once officially promulgated cannot be lowered except by some costly process of construction or alteration of property, or in the case of casualty insurance by some cycle of good luck in accident experience which may automatically reduce the cost of casualty protection.

For the public utility company insurance is a means of relief from the immediate payment of unexpected losses, a safeguard for uninterrupted service and a protection against catastrophe. Attention is particularly directed to that feature of protection applicable to continuity of service so essential in the public utility business. Service may be quickly and seriously impaired or discontinued by damage to the plant or equipment, and the consequent loss of business may impose a serious burden upon the company. To protect the investors and customers it becomes necessary to guard against such losses as may result from interrupted or discontinued services. Therefore proper coverage and protection measures should be employed, even though they be only for the prevention of consequential losses.

The electrical industry is now paying just rates of premium for fire insurance protection. This assurance was brought about several years ago and has been steadily maintained by the efficient and businesslike attention given to insurance costs by the insurance committees of the National Electric Light Association. The present committee and its predecessors have diligently kept a record of rates charged and losses sustained and have received the most hearty co-operation of the insurance interests in keeping the proper balance between these factors of rate determination. The appreciation of the members of the association is due its insurance committees and the co-operating agencies and representatives of standard fire insurance companies for this service, which has not only resulted in broader coverage, just rates and improved methods of fire prevention, but also in a better understanding of the mutual interests of the electrical and insurance industries.

### Possibilities of Cost Reduction

There is no intention, however, to cover the subject of insurance in the broad and general way indicated by what has been said, but to deal with the possibilities of economy in insurance costs and with a somewhat literal interpretation of this term as it is applied to the costs reflected in premiums paid for protection. Such costs when compared to payroll and other large operating items may not by such comparison alone appear to be of great importance, but if those costs are susceptible of material reductions, then their import becomes established. The task of reducing some of these larger expenditures to any appreciable extent may, and no doubt is, much more difficult than a reduction of insurance costs, and to properly evaluate the latter the possible savings rather than the comparative volume of expense should be kept in mind.

Structural changes in the physical property provide the more frequent opportunities for reduction of premium rates for both fire and casualty insurance. Recommendations for such changes in structure and the installation of safeguards usually emanate from the insurance broker or safety engineer and are often given little attention because of a preconceived idea that such recommendations are seldom practical or of material consequence. It is true that some of the recommended expenditures for changes may not be reflected in lower rates, but even these may be of great importance for the protection of the property or employees or in the interest of uninterrupted service.

### Reclassification of Payrolls

A proper classification of payrolls has a distinct bearing on just and proper rates charged for casualty insurance. This may be illustrated by the proper allocation of the payroll of office workers in the engineering department to the office classification payroll and the lower rate thereon, instead of to the classification of payroll and rate applying to other employees of this department who are exposed to construction hazards and properly subject to the higher rate. Frequent revisions and proper arrangement of payrolls in accordance with the several risks and differing rates should be made and may often result in substantial savings in liability insurance costs.

The third factor in all rate changes is that of loss experience. Herein lies the most prolific source of economy and the factor requiring special consideration. Loss experience is controllable. Time will not permit an amplification of this thought, about which so much has been said. It is sufficient to emphasize that the prevention of accidents and fires can be accomplished only by intelligent and constant attention such as is given to the other operations of the public utility. This attention must be assured by systematic plans of organization and by the interest and co-operation of every employee. Well-planned and efficient accident and fire prevention work will establish better employee and public relations, prevent service interruptions and eliminate those incidental costs of accidents and fires not covered by insurance.

The desirability of the insured to assume a part of the risk has always been recognized and made possible by the co-insurance provisions of insurance coverage. The proportion of the risk to be thus assumed by the insured depends upon the character of the risk and the ability of the insured to bear his proportion of the loss immediately. It is the usual practice for the insurer to assume four-fifths of the risk and for the insured to become a self-insurer for the remainder. The question as to what proportion of risks, or as to total risks, which may properly be considered for self-insurance is particularly apropos for public utility companies. This is especially true of those engaged in the manufacture and distribution of electrical energy who maintain metropolitan plants of large values or those whose properties are established over wide areas with widely distributed units of value. Such companies have exceptional opportunities and advantages for economies in insurance costs through self-insurance plans.

By such plans properly and soundly established economies are possible through the elimination of large administration expenses, including acquisition costs imposed upon standard insurance companies. There are other advantages in dealing directly and justly with injured employees and the public, reflected in a closer and better relationship with these possible claimants.
